Model organisms: Mouse

Hans Bluyssen, 01.04.2021

What are model organisms?

A model organism is a species that has been widely studied, usually because it is easy to maintain and breed in a laboratory setting and has particular experimental advantages.

Model organisms are non-human species that are used in the laboratory to help scientists understand biological processes.

What are model organisms?

For example, they may have particularly robust embryos[?] that are easily studied and manipulated in the lab, this is useful for scientists studying development.

Or they may occupy a pivotal position in the evolutionary tree, this is useful for scientists studying evolution.[?]

Why are model organisms useful in genetics research?

Many model organisms can breed in large numbers.
Some have a very short generation time, which is the time between being born and being able to reproduce, so several generations can be followed at once

Mutants allow scientists to study certain characteristics or diseases. These are model organisms that have undergone a change or mutation[?] in their DNA[?] that may result in a change in a certain characteristic.

Why are model organisms useful in genetics research?

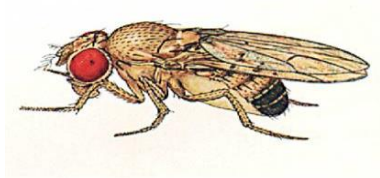
Some model organisms have similar genes[?] or similar-sized genomes[?] to humans.

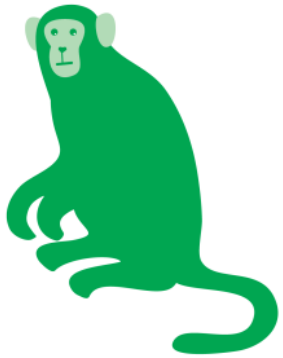
Model organisms can be used to create highly detailed genetic maps:

Genetic maps are a visual representation of the location of different genes on a chromosome[?], a bit like a real map but one where the key landmarks are areas of interest in the genome. For example, areas of DNA that differ between individuals in the same species (SNPs[?]) or genes.

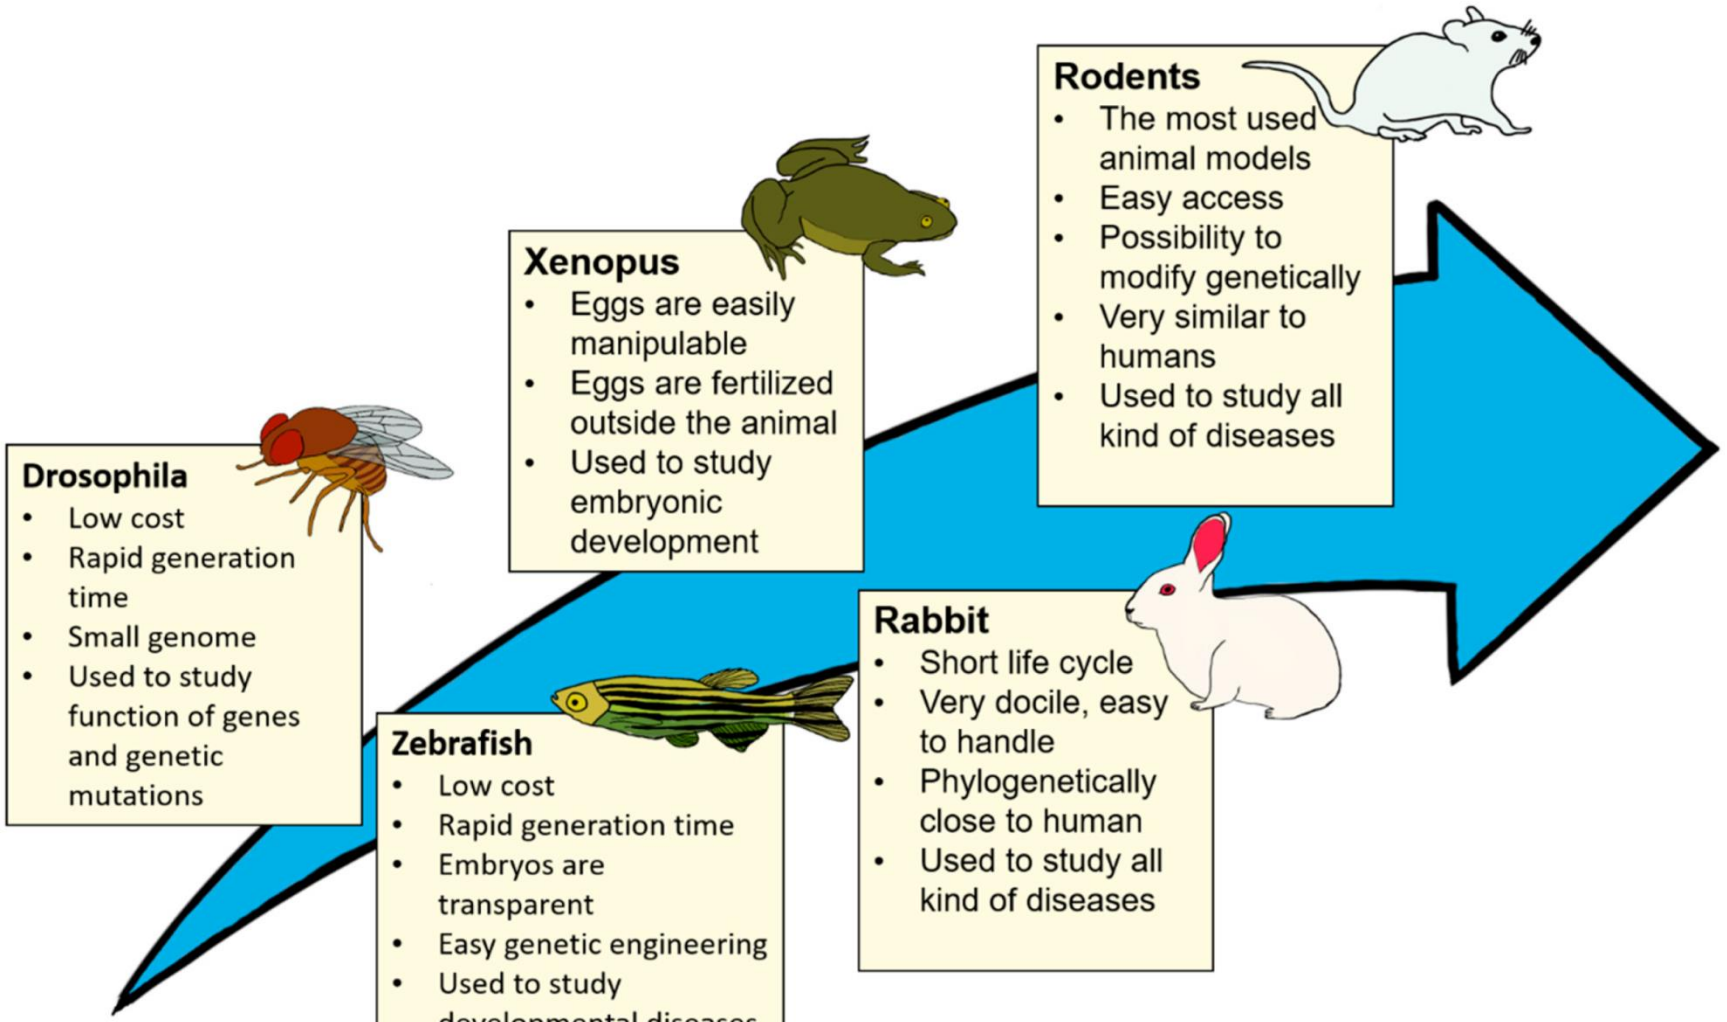
Examples of model organisms used to study genetics

Yeast (*Saccharomyces cerevisiae*)
Fruit fly (*Drosophila melanogaster*)
Nematode worm (*Caenorhabditis elegans*)
Western clawed frog (*Xenopus tropicalis*)
Mouse (*Mus musculus*)
Zebrafish (*Danio rerio*)
Monkey (*Macaca mulatta)*





Examples of model organisms used to study genetics



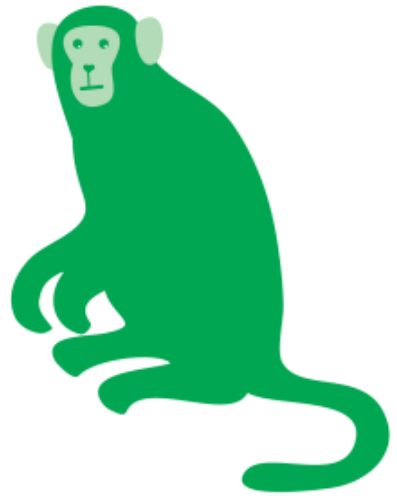
Drosophila
- Low cost
- Rapid generation time
- Small genome
- Used to study function of genes and genetic mutations

Zebrafish
- Low cost
- Rapid generation time
- Embryos are transparent
- Easy genetic engineering
- Used to study developmental diseases

Xenopus
- Eggs are easily manipulable
- Eggs are fertilized outside the animal
- Used to study embryonic development

Rabbit
- Short life cycle
- Very docile, easy to handle
- Phylogenetically close to human
- Used to study all kind of diseases

Rodents
- The most used animal models
- Easy access
- Possibility to modify genetically
- Very similar to humans
- Used to study all kind of diseases



MACAQUE MONKEY
Macaca mulatta

- Genetically similar to humans
- Similar immune responses to humans
- Useful for longitudinal studies

Examples of model organisms used to study genetics

Disease modeling of human inherited kidney disease

- Pathomechanisms
- Genetics:
  - Forward mutagenic screens
  - Validation of variants pathogenicity
- Precision medicine
- Identification of therapeutic targets and drug testing

House mouse: Facts

-Over the past century, the house mouse (*Mus musculus*) has become the preferred mammalian model for genetic research.

-In the early days of biomedical research, scientists developed mouse models by selecting and breeding specific mice to produce offspring with certain desired characteristics.

-Now scientists use mice to simulate human genetic disorders in order to study their development and test new therapies.

-As a scientific tool, mice have helped to speed up the progress of research and enabled the development of important new drugs.

-The genome sequence is approximately 3,500 million base pairs in length and contains over 23,000 protein-coding genes (Ensembl).

House mouse: Benefits

-Have many similarities to humans in terms of anatomy, physiology and genetics.
-Similar genome, making mouse genetic research particularly useful for the study of human diseases.
-Mice are small and cost effective: they are cheap and easy to look after.
-Multiply quickly: reproduce as often as every three weeks creating lots of offspring.
-Generation time is short, around 10 weeks: several generations can be observed at once.
-Have a short lifespan (one mouse year equals about 30 human years) which means scientists can easily measure the effects of ageing.
-Are extremely useful for studying complex diseases[?], such as atherosclerosis and hypertension, as many of the genes responsible for these diseases are shared between mice and humans. Research in mice provides insights into the genetic risk factors for these diseases in the human population.

House mouse: Benefits

-It is relatively easy to manipulate the mouse genome, for example, adding or removing a gene to better understand its role in the body. This provides a powerful tool for modelling specific diseases when a mutated gene is known to play a role in the disease.
-Mice are far better than flies or worms for studying complex biological systems found in humans, such as the immune, endocrine (delivers hormones? into the body), nervous, cardiovascular and skeletal systems. Like humans, mice naturally develop diseases that affect these systems, including cancer? and diabetes?.
-Immunodeficient mice (mice without a fully functioning immune system) can also be used as hosts to grow both normal and diseased human tissue. This has been a useful tool in cancer? and AIDS? research.

Examples of mouse models?

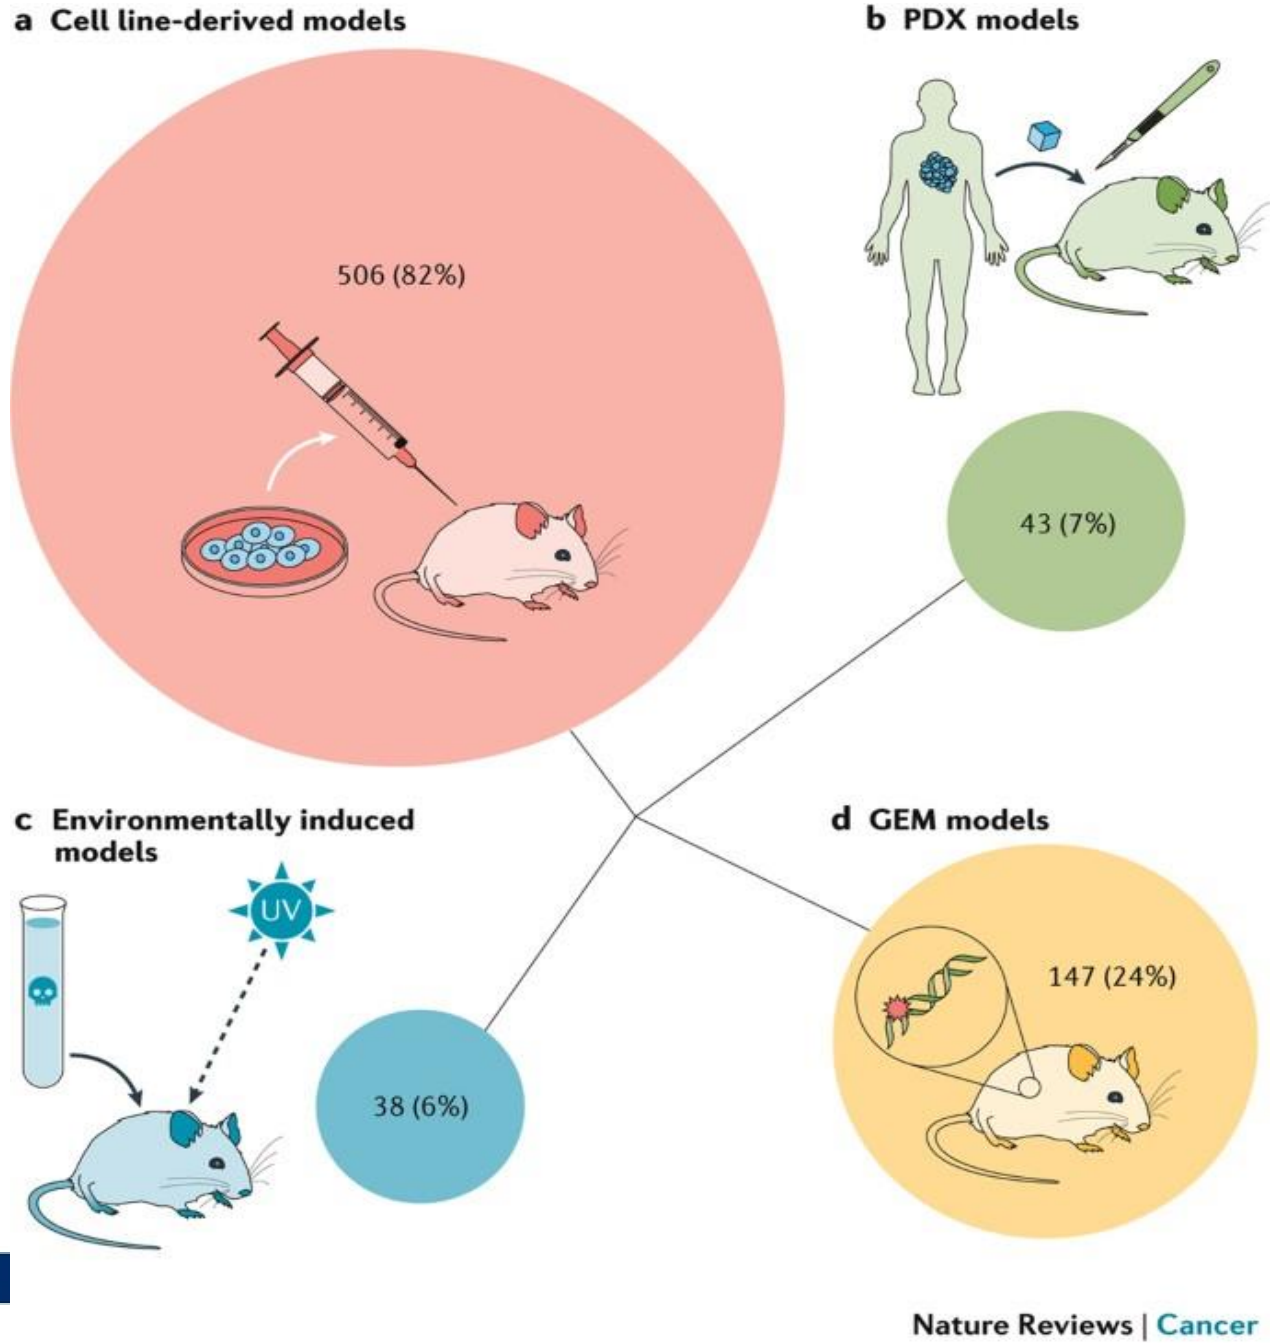
Genetically modified mouse

A genetically modified mouse or genetically engineered mouse model is a mouse that has had its genome altered through the use of genetic engineering techniques.

Genetically modified mice are commonly used for research or as animal models of human diseases, and are also used for research on genes.

“Transgenic mouse”

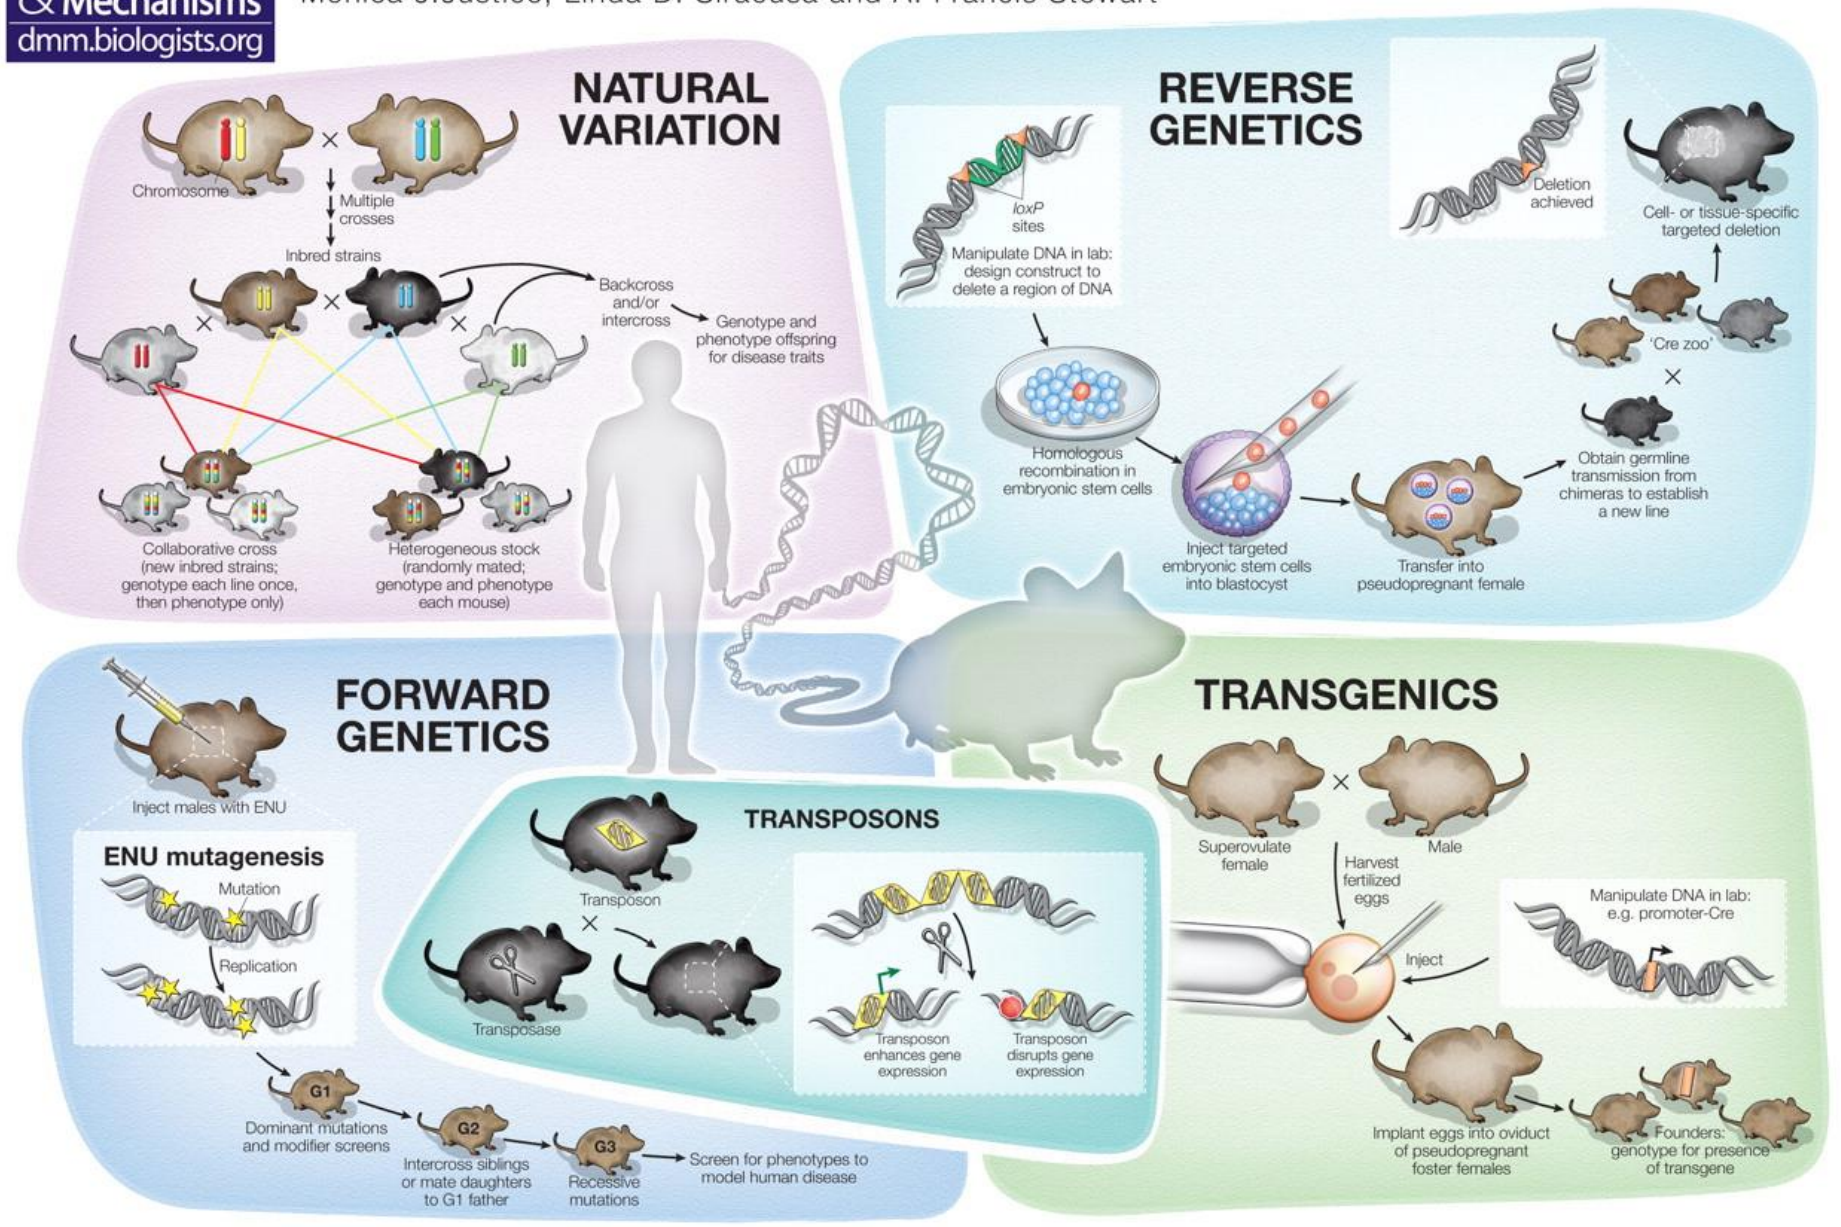
Examples of mouse models



Patient derived xenografts are models of cancer where the tissue or cells from a patient's tumor are implanted into an immunodeficient or humanized mouse

Genetically engineered mouse models

Examples of mouse models



Embryonic Stem cells

Zygotes

Examples of mouse models

Mouse model	Possible phenotypes	Some uses and questions
Transgenic Multiple copies of exogenous DNA 	•Phenotype severity often depends on transgene copy number; possible artifacts from overexpression and from insertion site of transgene	•Investigating later-stage disease mechanisms •Can late-stage disease be treated?
Knockin Replace mouse sequence with another sequence expressed physiologically 	•Phenotype may appear in mid- and late-life; may be mild	•Investigating earlier-stage disease mechanisms •When does disease start? •Can we treat prodromal/presymptomatic disease? •Can we develop biomarkers?
Genomically humanized Replace mouse sequence with the orthologous human genomic region 	•Phenotype may appear in mid- and late-life; may be mild	•Investigating earlier-stage disease mechanisms •When does disease start? •Can we treat prodromal/presymptomatic disease? •Can we develop biomarkers? •Do human proteins behave differently from mouse proteins?
Chromosome engineered aneuploidy A chromosomal region is duplicated or deleted 	•Phenotype may be mild	•Investigating dose-sensitive genes/mechanisms •Dose-sensitive gene mapping •Investigating disease mechanisms and biomarkers
Transchromosomal model Human chromosome added to the mouse genome 	•Phenotype may be mild •Expressing mouse and human genes	•Investigating dose-sensitive genes/mechanisms •Dose-sensitive gene mapping •Investigating disease mechanisms and biomarkers •Investigating human genomic DNA function in a mouse cellular environment
Chimeras, mouse-mouse, and human-mouse Mice consisting of two different cell lines, e.g., mouse-mouse or mouse-human 	•Phenotype may be mild but depends on the cell lines used, which could be wildtype or genetically manipulated	•How does pathology spread? •Is disease cell autonomous? •Do human cells behave differently from mouse cells?
Inducible and conditional Temporal or spatial control of gene expression 	•Phenotypes vary depending on the genetic manipulation	•Investigating protein function •Investigating temporal/spatial specificity in pathogenesis •Which cell types are key to pathogenesis? •Is disease cell autonomous? •Is disease reversible?
Knockout Functionally delete a gene 	•Phenotypes vary but often are severe in null animals	•Investigating loss of function •What are loss-of-function effects?

Mouse models of Human Disease

Why Use Transgenic Mouse Models?

- Model specific aspects of a human disease
- Test drugs or other treatments in a controlled system

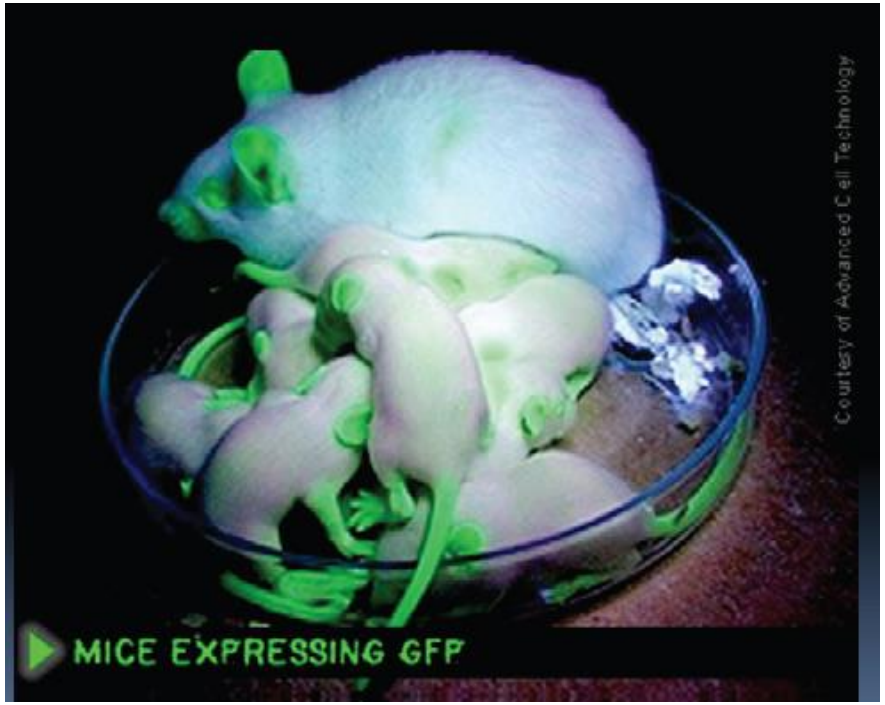
- Highlight the function of your gene of interest
- Cross to different lines to expand experimental possibilities

ingenious targeting laboratory

Transgenic and knockout mice

A transgenic animal is much more complex than working with cultured cells

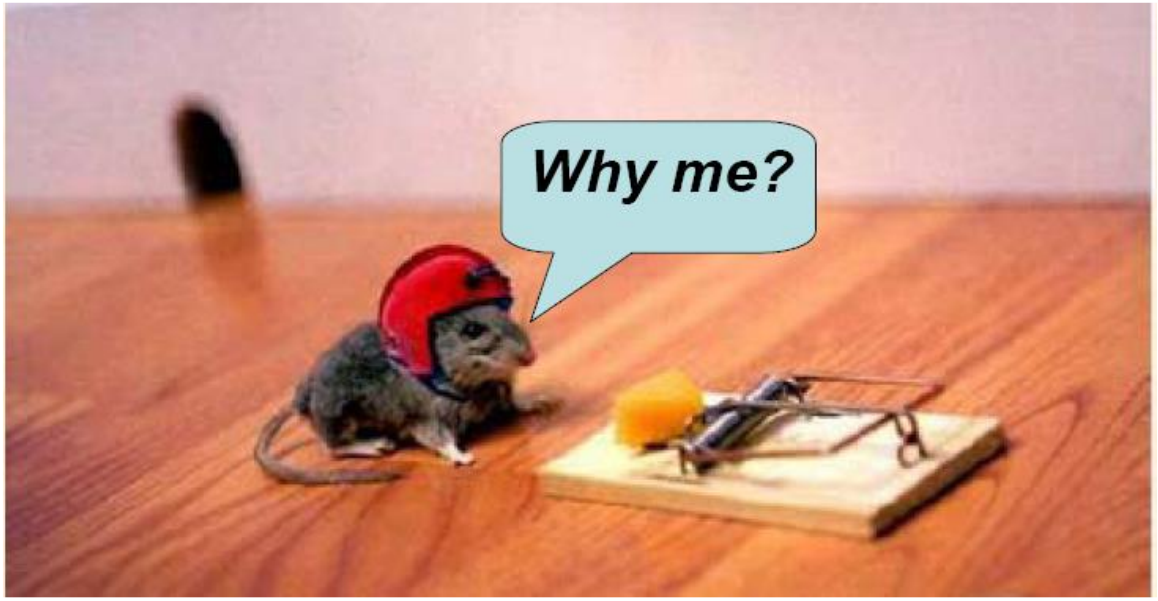
Transgenics can be used for a variety of purposes, covering both basic research and biotechnological applications



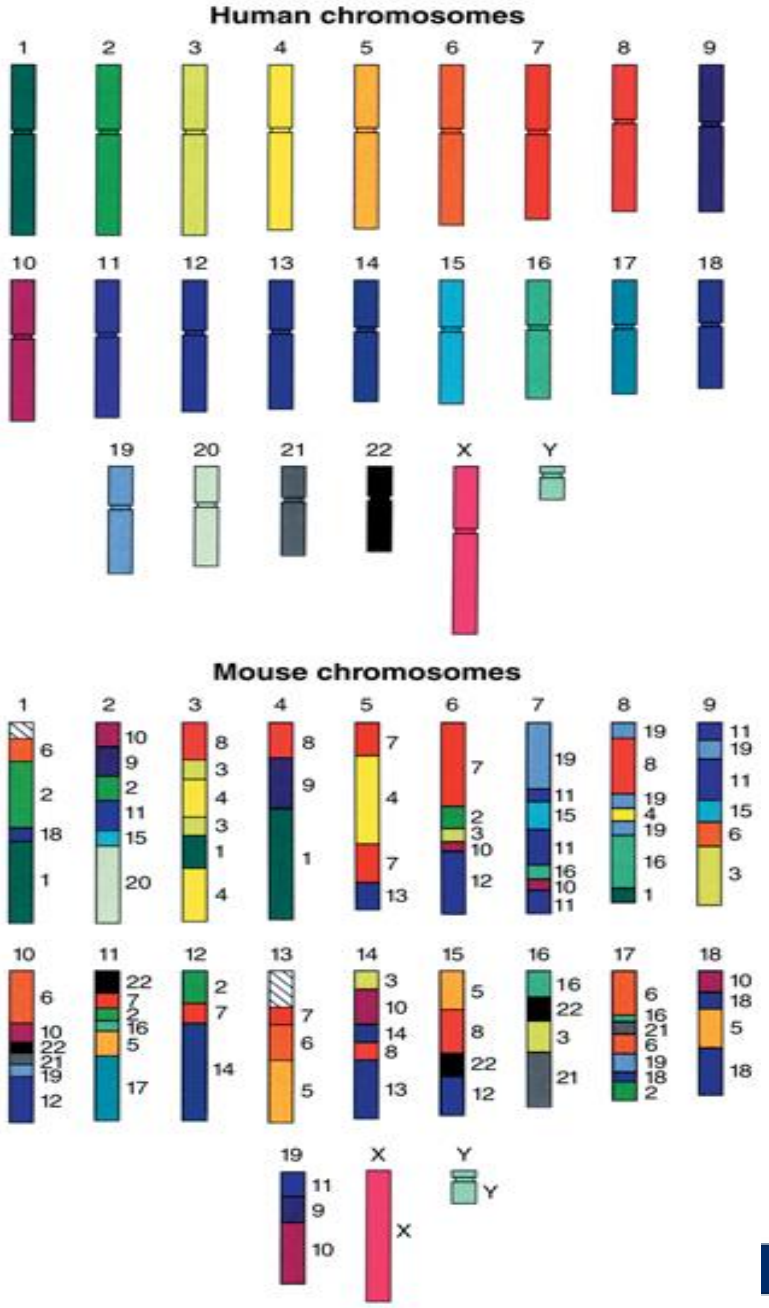
Transgenic and knockout mice

Mice have 19 autosomal chromosomes and two sex-chromosomes (X and Y), many of which contain large segments of DNA that are **highly conserved between mouse and humans**.

One of the goals of mouse transgenesis, is to use molecular genetic approaches to **create better mouse models of human diseases** that are based on known genetic lesions.



The mouse is a reliable stand-in for humans in medical research, thanks to a genome that is 85 percent identical.



Transgenic and knockout mice

Synteny: The co-localization of genes on chromosomes of related species.

Homolog: The situation where nucleic acid or protein sequences are similar because they have a common evolutionary origin. Often used loosely to indicate that sequences are very similar.

Ortholog – gene sequences are similar between species.

Paralog – gene sequences are similar within a species.

Adapted from the Department of Energy; genomics.energy.gov

Transgenic and knockout mice

Disease Mode	Gene
Cystic Fibrosis	CFTR
Atherosclerosis	Apo E, apo (a), Apo A-II
anti-Atherosclerosis Gene Therapy	Apo AI, Ape E, LDLR
B-Thalassemia	ß -globin
Sickle Cell Anemia	$ß^S$ (and variants)
Inflammatory Bowel Disease	Interleukine-2, Interleukin-10 and T-cell Receptor ,ß ; MHC II
Severe Combined Immunodeficiency Disease	Rag-1, Rag-2
Muscluar dystrophy Gene Theraphy	Dystrophin
Alzheimers disease	ß -amyloid
Amyotrophic lateral sclerosis (ALS)	neurofilament heavy chain
Insulin Dependent Diabetes Mellitus	interferon-
Cancer	many oncogenes and tumor supressor genes

Transgenic and knockout mice

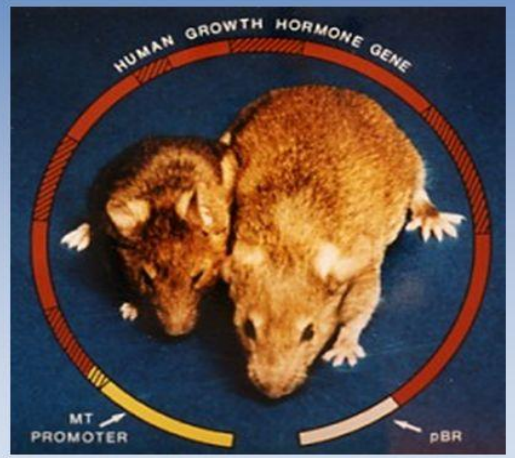
- Example: Transgenic Mice (hair gene removed)
- Used to help burn patients and others by making human facial parts (ears, nose lips, etc.)

https://www.youtube.com/watch?v=kefoIXnLAN0

Transgenic and knockout mice

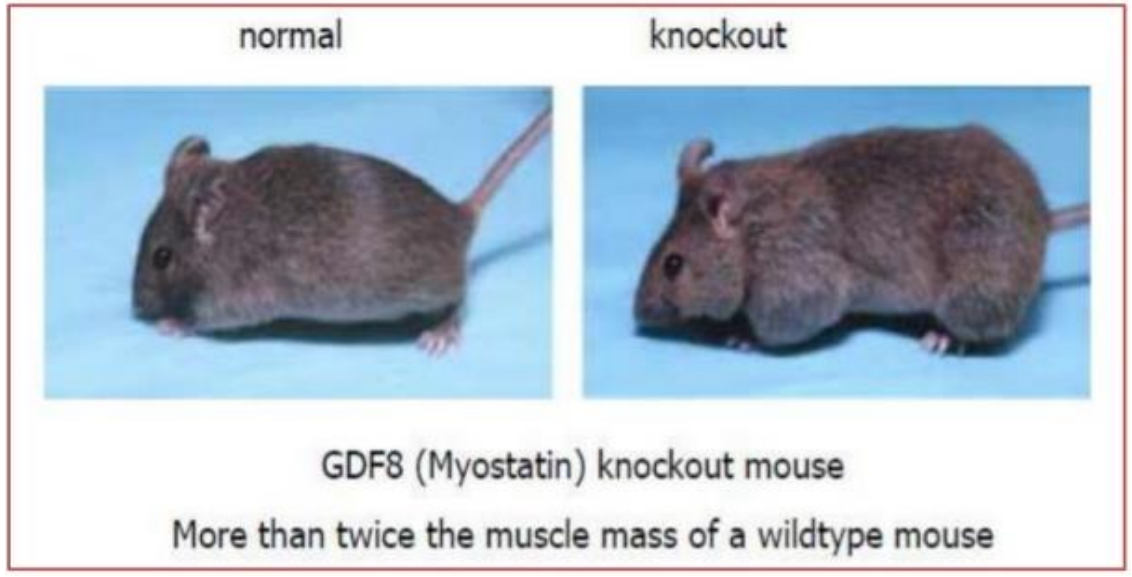
Example

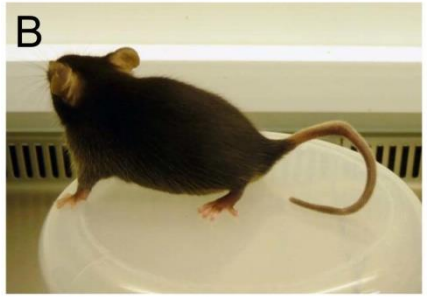
- Comparison between a transgenic mouse and a normal mouse
- The giant mouse developed from a fertilized egg transformed with a recombinant DNA molecule containing the Human Growth Hormone



➢ Knocking out expression of Nhlh2, a basic helix-loop helix transcription factor in mice results in adult onset obesity.

Transgenic and knockout mice





A chimeric mouse gene Targeted for the Agouti Color gene, with its offspring

Using mouse models in Progeria

Transgenic and knockout mice

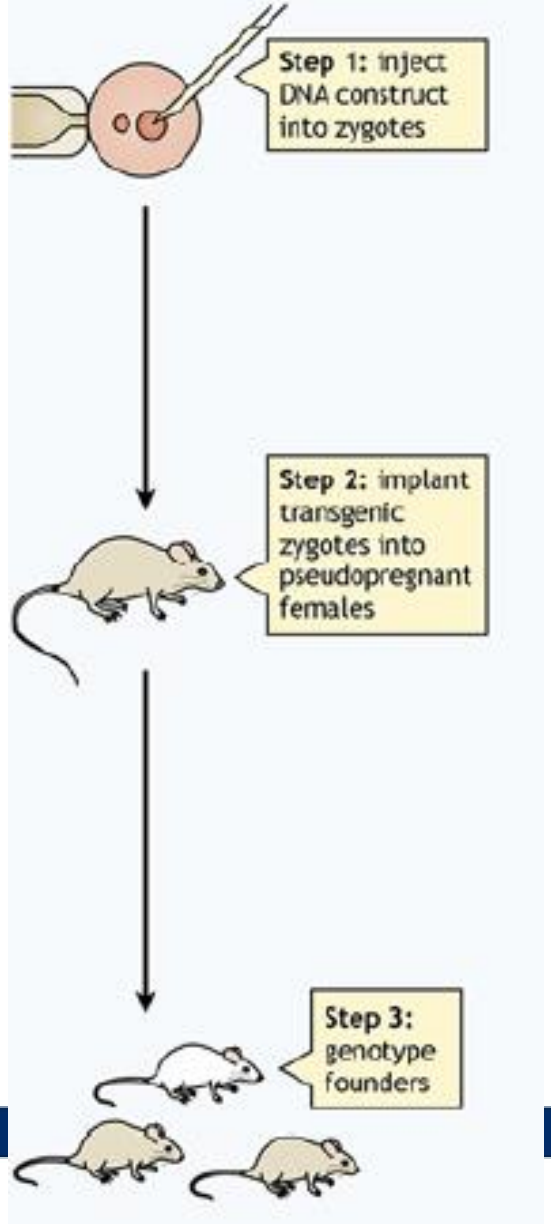
- **Spontaneous Mutants**
  - Occurs as the result of spontaneous mutation
  - Examples:
    - db/db (Diabetic mouse)
    - nu/nu (Nude mouse)

- **Induced Mutants**
  - Transgenics
    - Overexpression
    - Inducible / conditional

  - Gene targeting
    - Knock-outs
    - Knock-ins

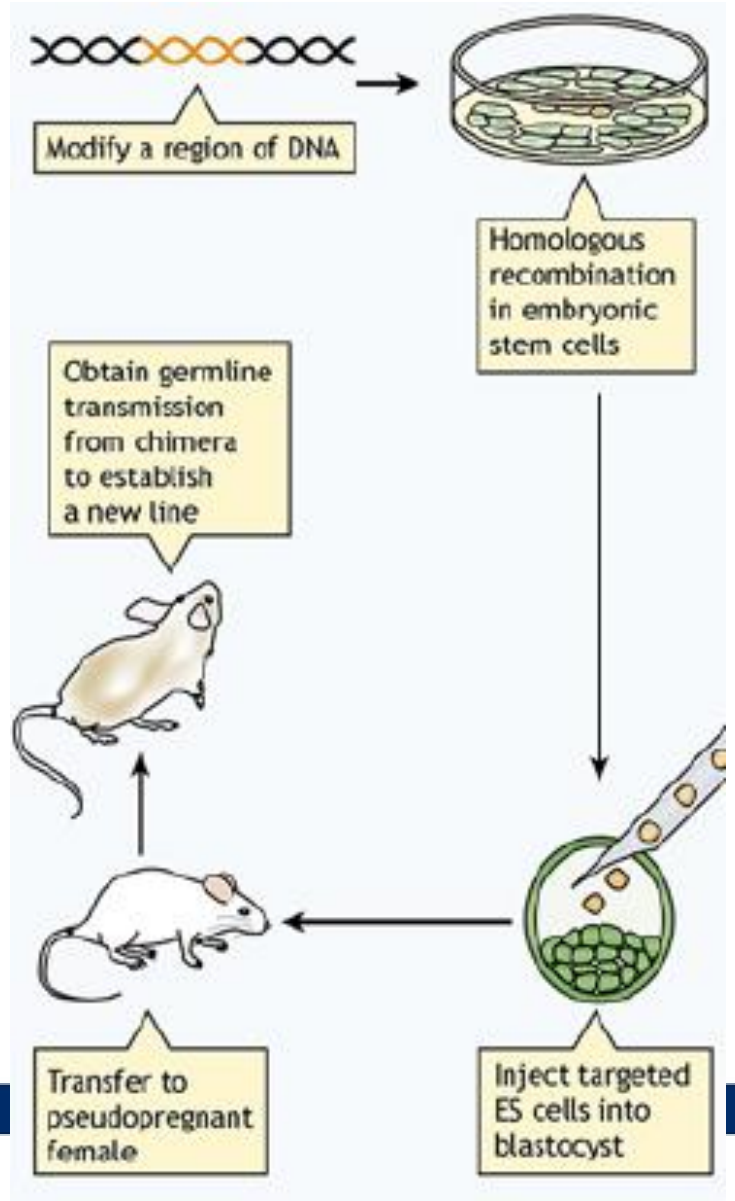
  - Mutagenic Mice:
    - Chemical mutagenesis of Embryonic Stem cells
    - Chemical mutagenesis / Irradiation of Mice

Producing Transgenic mice

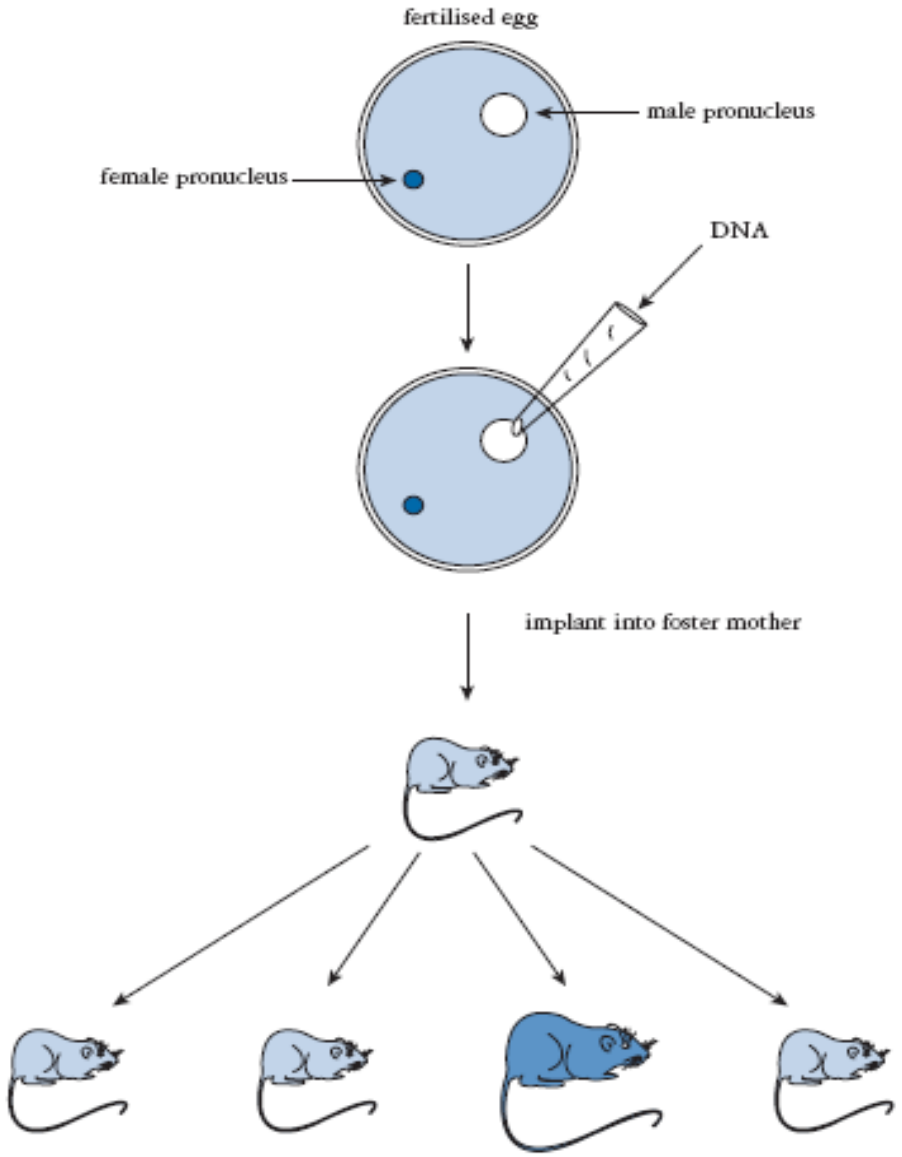


Pronuclear Injection

Gene Targeting in ES Cells



Producing Transgenic mice



A **pronucleus** (plural: **pronuclei**) is the nucleus of a sperm or an egg cell during the process of fertilization. The sperm cell becomes a pronucleus after the sperm enters the ovum, but before the genetic material of the sperm and egg fuse.

Aim: to alter the germ line so that the genetic change is inherited in a stable pattern

Production of transgenic mice – the construct

Transgenes should include:

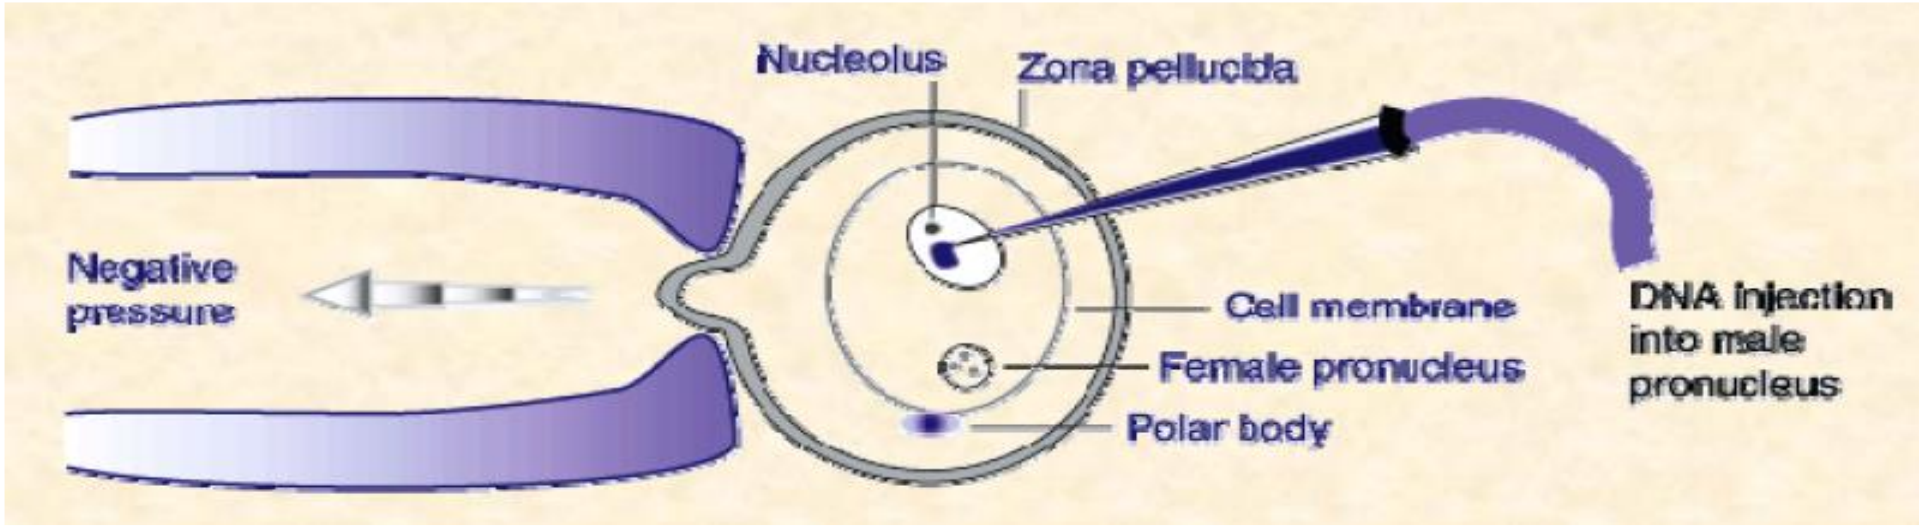
- Promoter, with or without enhancer
- Gene to be expressed, which may be a reporter gene
- Splice donor and acceptor sequences flanking an intron, these can be from another gene, e.g. beta-globin or SV40 t antigen
- Termination/polyadenylation sequences, these can be from another gene, e.g. beta-globin or SV40 t antigen

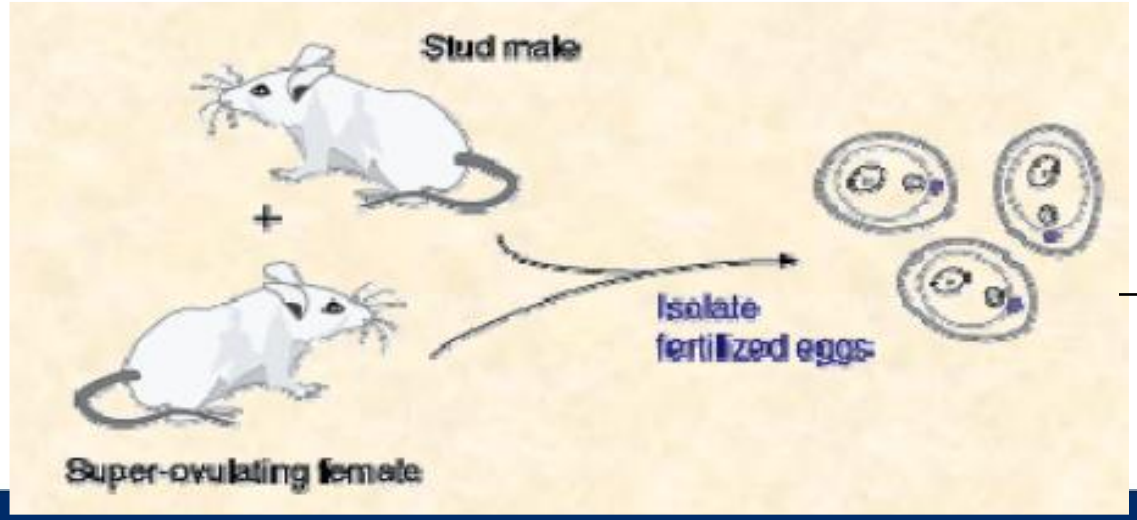
- **Transgenes must be excised from the bacterial plasmid sequences in order to be expressed in mice**
  - This is because the prokaryotic cloning vector sequences inhibit expression of eukaryotic genes introduced into the mouse genome.

Random Integration

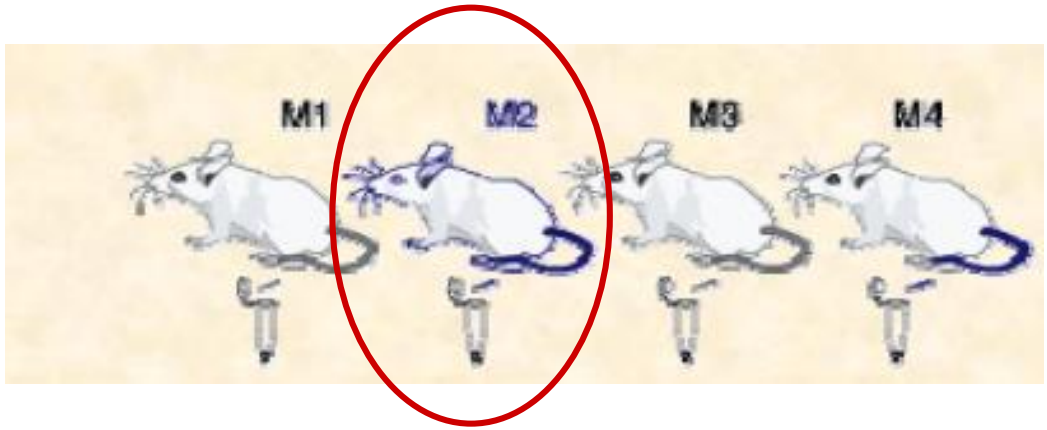
→ Sequences ensuring expression of the transgene

Production of transgenic mice - Introduction of genes into embryos

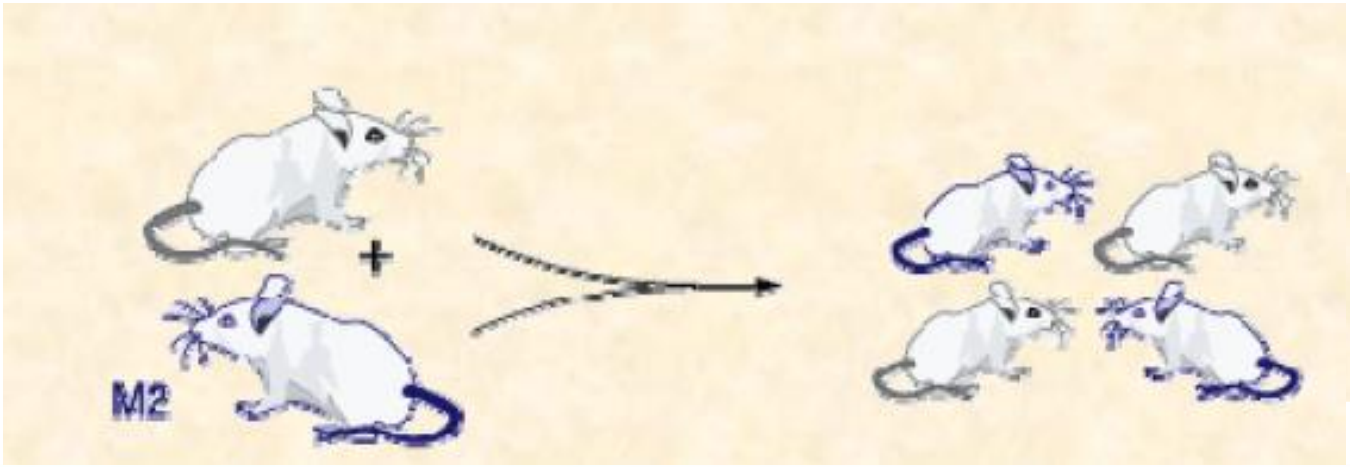




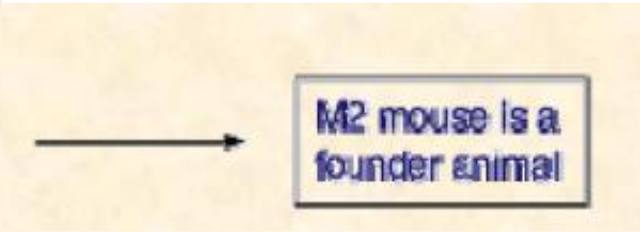
Producing Transgenic mice



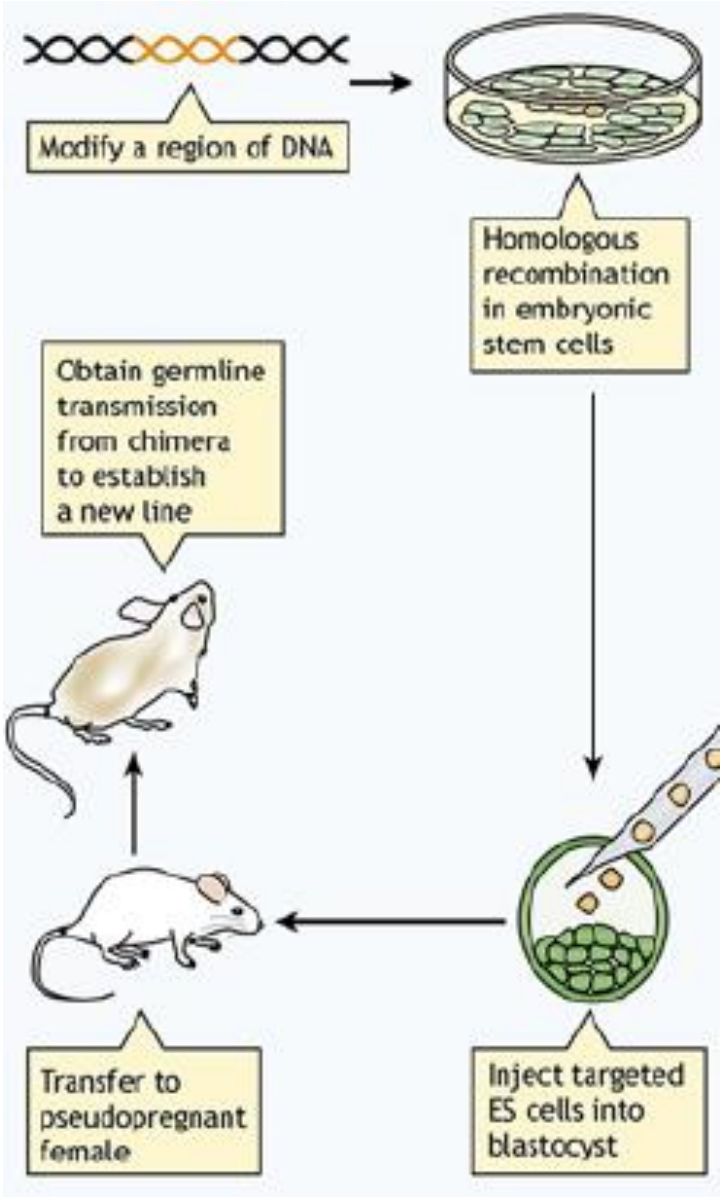
M2 is **backcrossed to non-transgenic mates** to identify **founder animals containing germline DNA** integration that results in a Mendelian inheritance pattern of the transgene.



Germline transmission



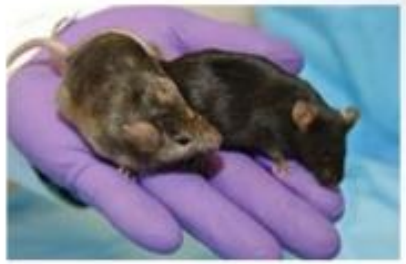
Gene Targeting in ES Cells



KO mouse

Gene Targeting in ES Cells

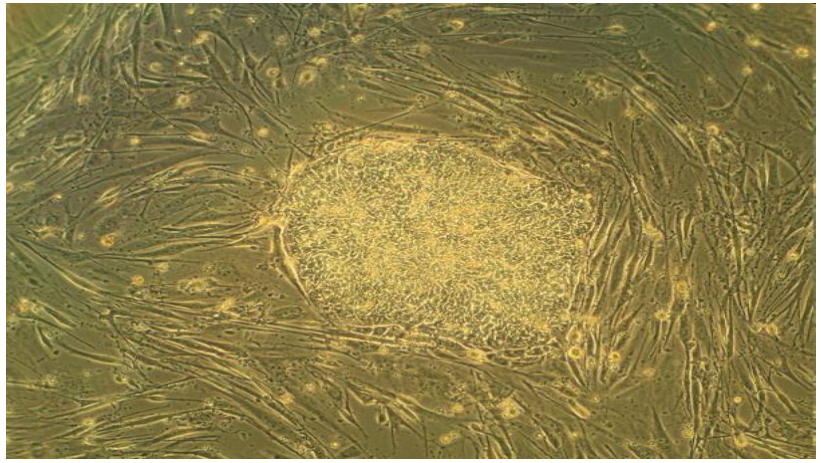
KNOCK OUT MICE



- a mouse in which a gene has been deleted/mutated (gene is inactivated)
- *specific* gene is targeted
- The loss of gene activity often causes changes in a mouse's phenotype and thus provides valuable information on the function of the gene.

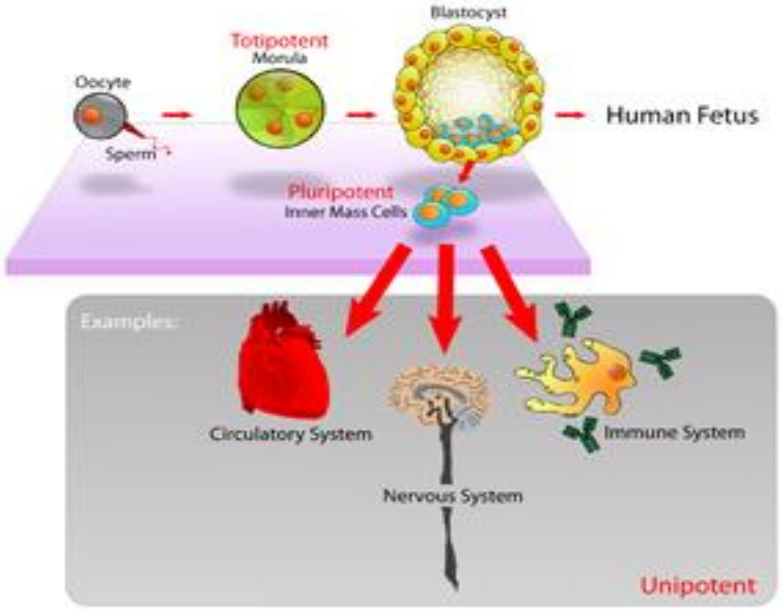
Production of transgenic mice using ES cell technology

Embryonic stem cells (ES cells) are stem cells derived from the inner cell mass of an early stage embryo known as a blastocyst.



embryos reach the blastocyst stage 4–5 days post fertilization ~they consist of 50–150 cells.

ES cells are pluripotent- are able to differentiate into all derivatives of the three primary germ layers: ectoderm, endoderm, and mesoderm.

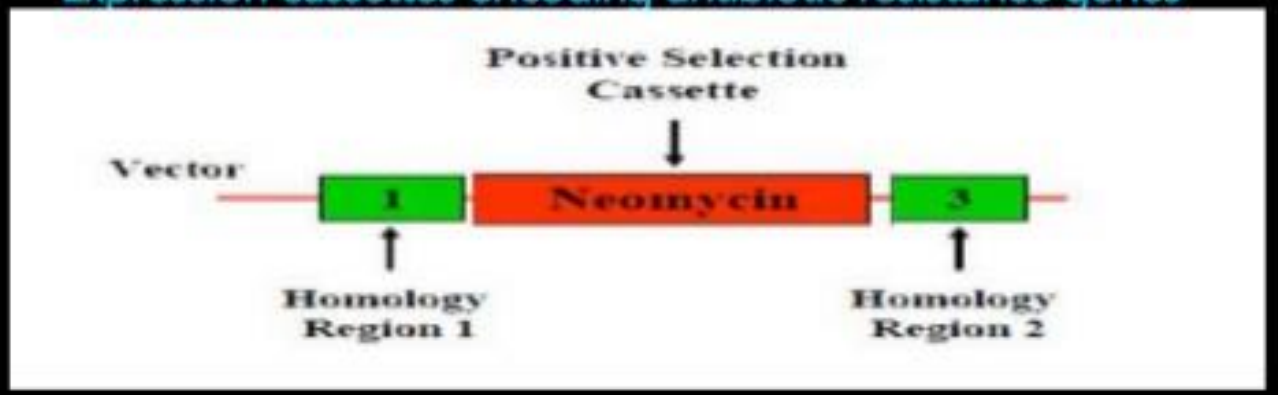


These include each of the more than 220 cell types in the adult body

Gene Targeting in ES Cells

TARGETING CONSTRUCT FOR POSITIVE / NEGATIVE SELECTION

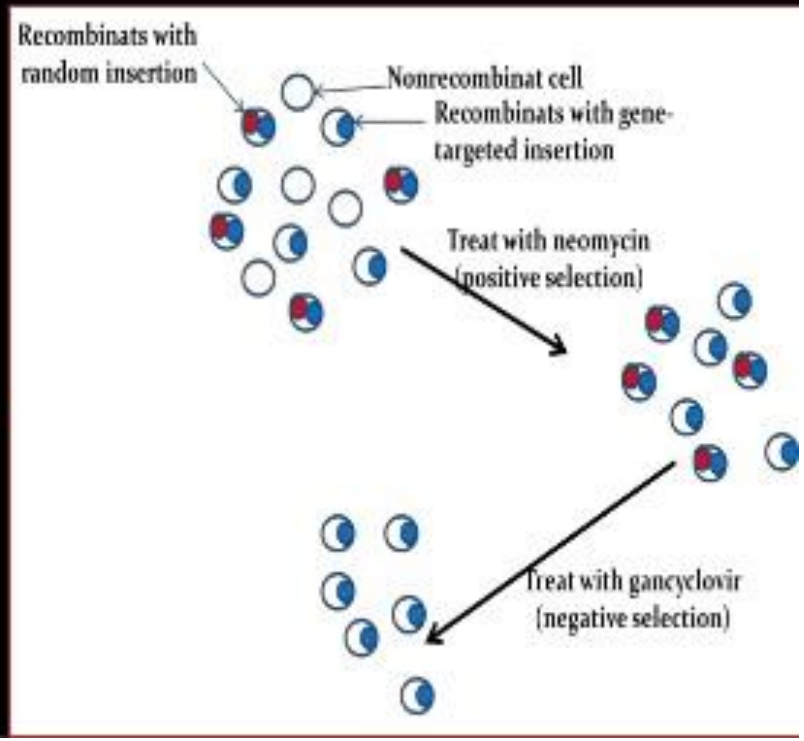
- To make targeting construct:
  - a positive selectable marker flanked by two "arms" of homologous sequence
  - a negative selectable marker outside one homologous arm
- **Positive selection markers**
  - Expression cassettes encoding antibiotic resistance genes



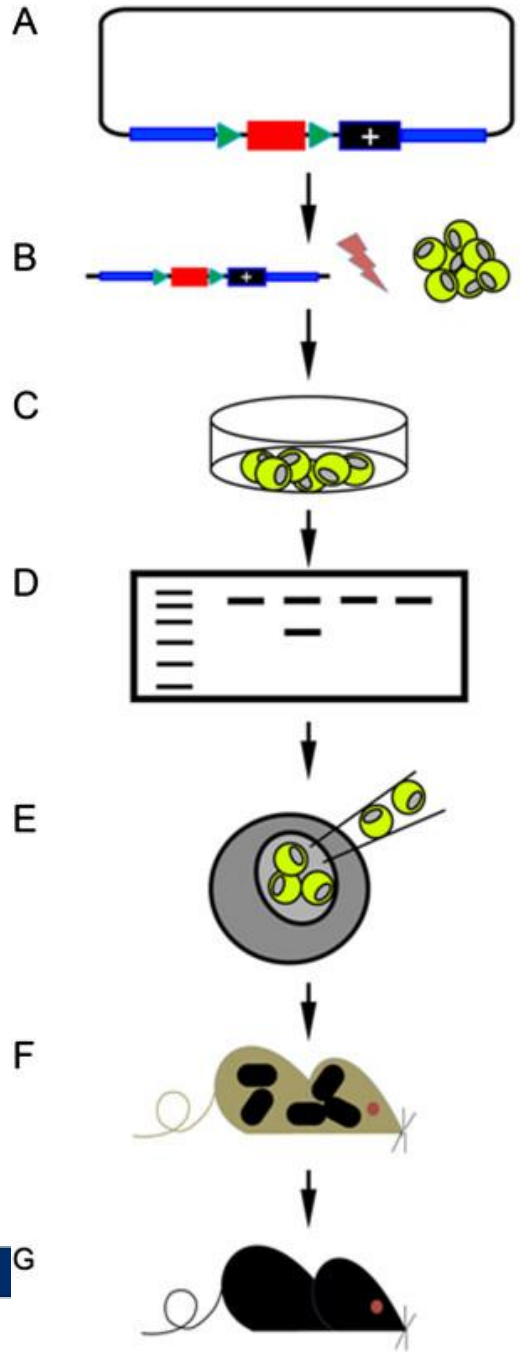
Gene Targeting in ES Cells

SELECTION STRATEGY

- **Positive Selection**
  - G418
  - Neomycin Resistance gene
  - confers resistance to G418
- **Negative Selection**
  - Gancyclovir
  - Herpes Simplex Virus Thymidine Kinase (HSV-TK) gene.
  - sensitive to gancyclovir
  - selects against random integrants



Gene Targeted Mice



A Generate the cko targeting vector.

B Electroporate the vector into ES cells.

C Culture ES cells in the presence of selectant and pick resistant colonies.

D Identify the ES cell clones with desired targeting either by Southern blot analysis or long range PCR.

E Microinject targeted ES cell clones into blastocysts and transplant into uterus of pseudopregnant female mice.

F Identify chimeric pups.

G Generate progeny that carry the targeted allele.

Gene Targeted Mice

Knockout systems – a variation on the theme

1. Conditional knockouts

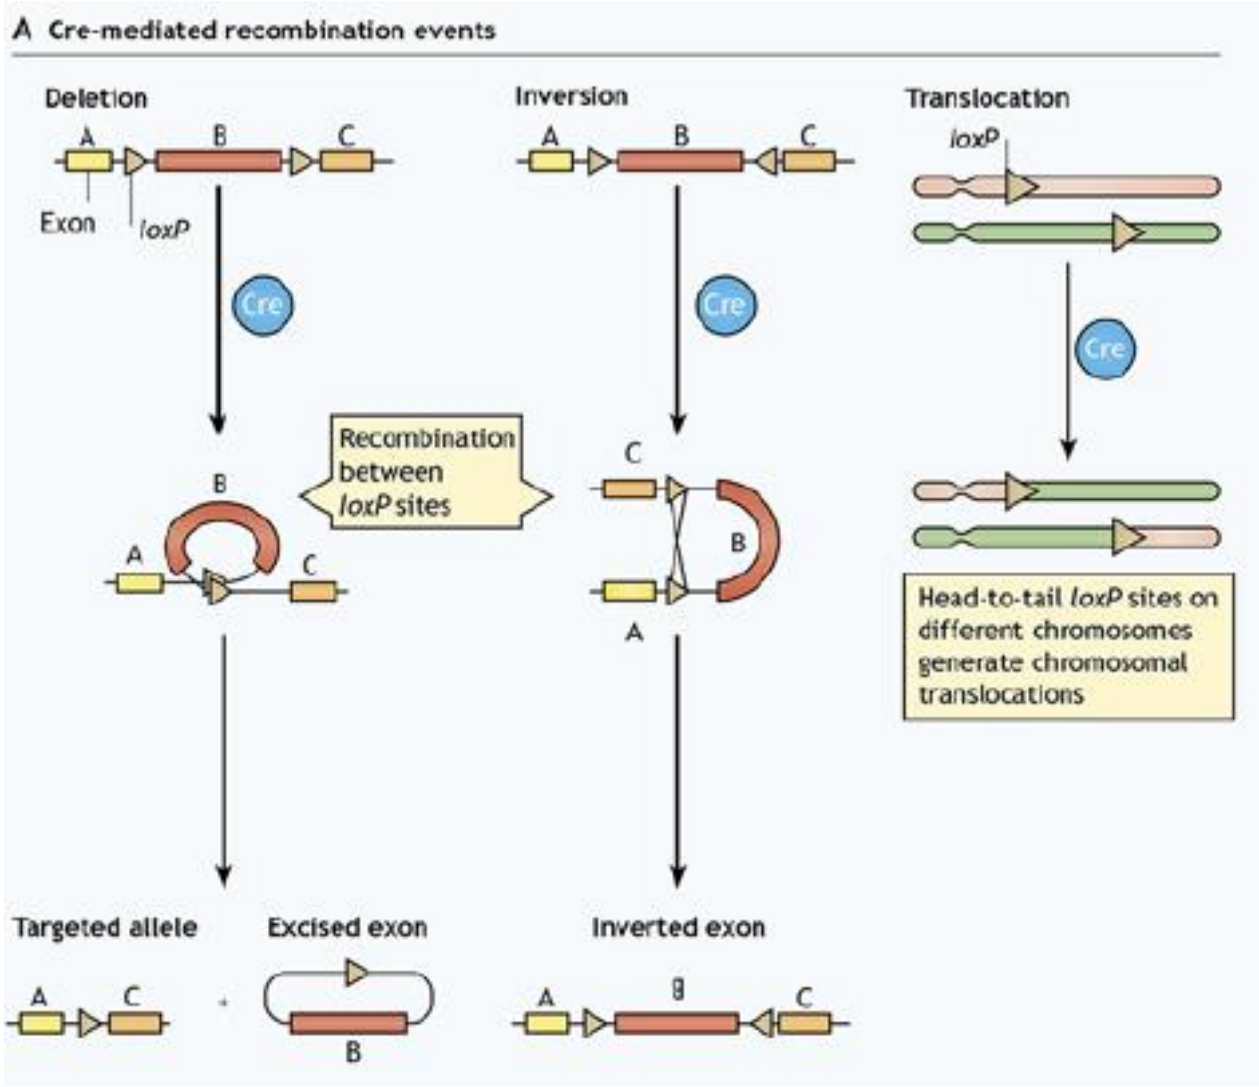
2. Knockin models (an additional gene function is established)

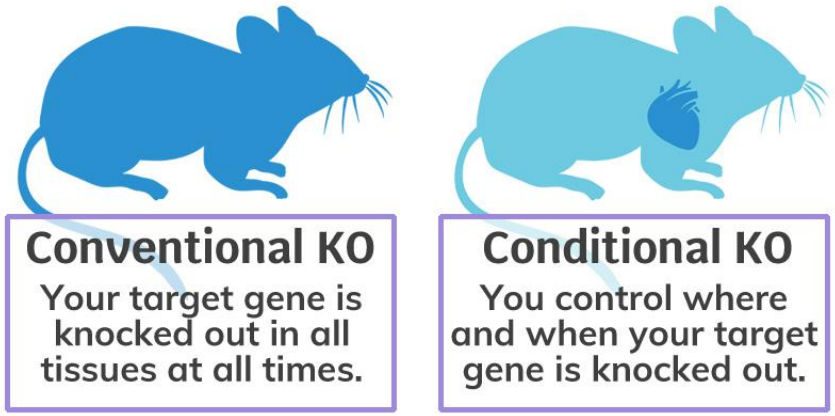
lacZ gene as a means of detecting tissue-specific gene expression

In 1995 a database was established to collate details of knockout mice. This is known as the **Mouse Knockout and Mutation Database**
There are over 5 000 entries in the Mouse Knockout and Mutation Database, which is a major resource for those interested in using the mouse as a model system for the study of gene expression, development, and disease.

MKMDcan be found at [http://research.bmn.com/mkmd

Conditional Mutagenesis



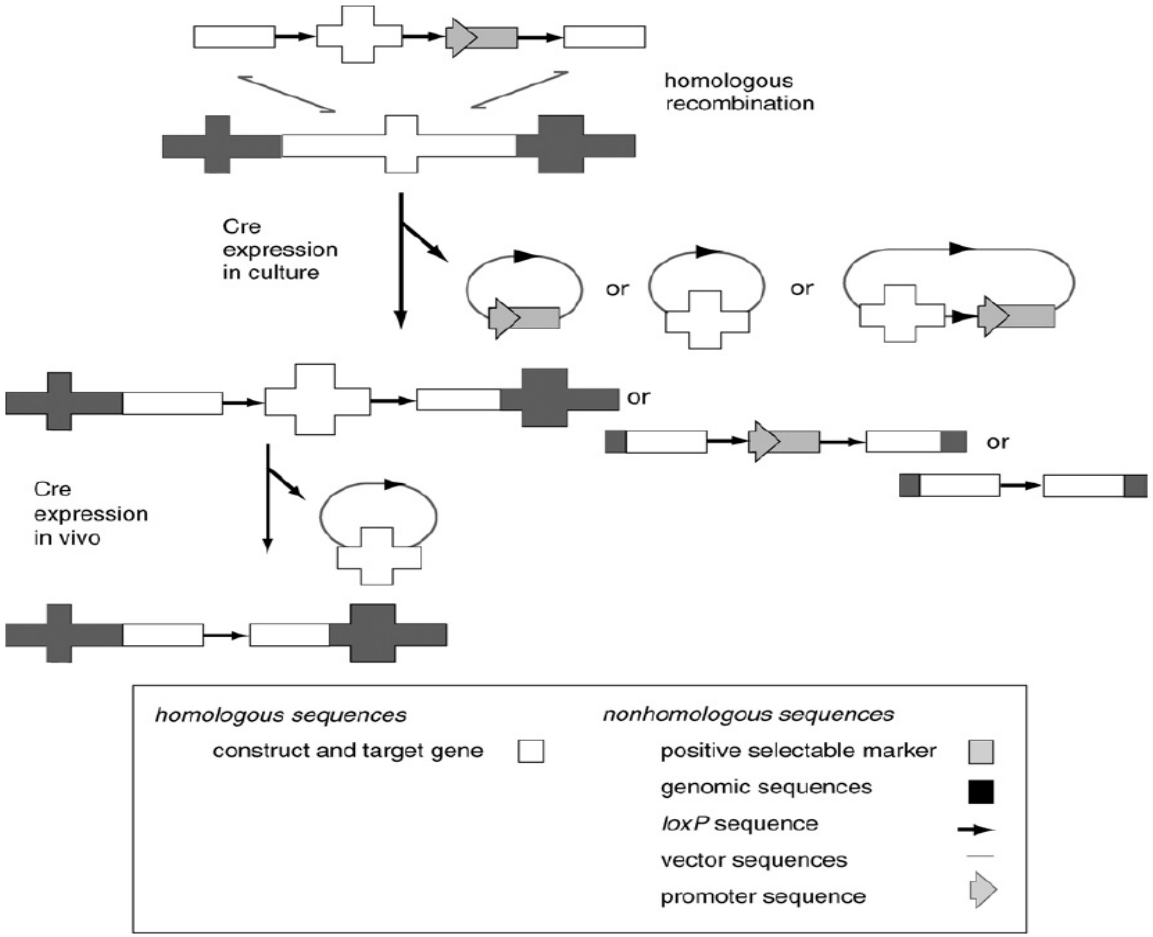


Cre-Lox recombination –

The *Cre-lox system* is used as a genetic tool to control site specific recombination events in genomic DNA. This *system* has allowed researchers to manipulate a variety of genetically modified organisms to control gene expression, delete undesired DNA sequences and modify chromosome architecture.

Knockout systems – the variation on the theme

Conditional gene targeting using the Cre/loxP system



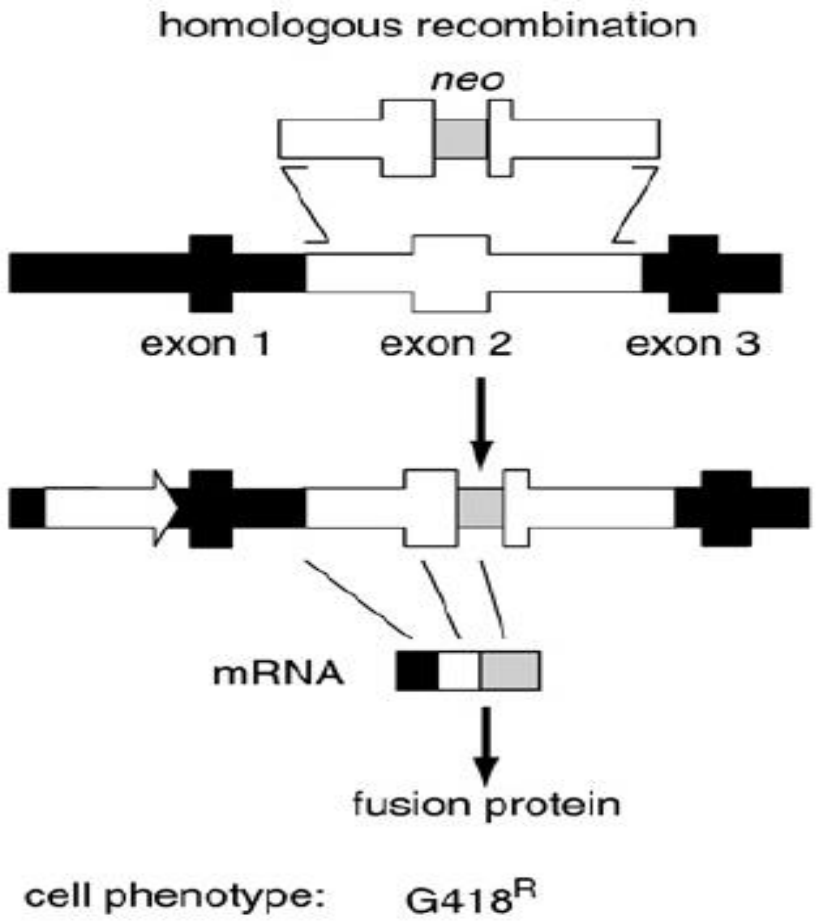
The targeting vector contains three loxP sites that flank the regions of the gene to be removed and the positive selectable marker neo.

After HR the selectable marker is excised - transient expression of Cre.

The correct recombination is identified by screening by Southern analysis or PCR.

The mutant ES cells are then used to produce mice

Using the Cre/loxP system to introduce subtle mutations



The subtle mutation is introduced along with the selectable marker in the targeting vector.

The selectable marker is then removed by transient expression of Cre, which leaves only the subtle mutation and the small loxP site in a silent location.

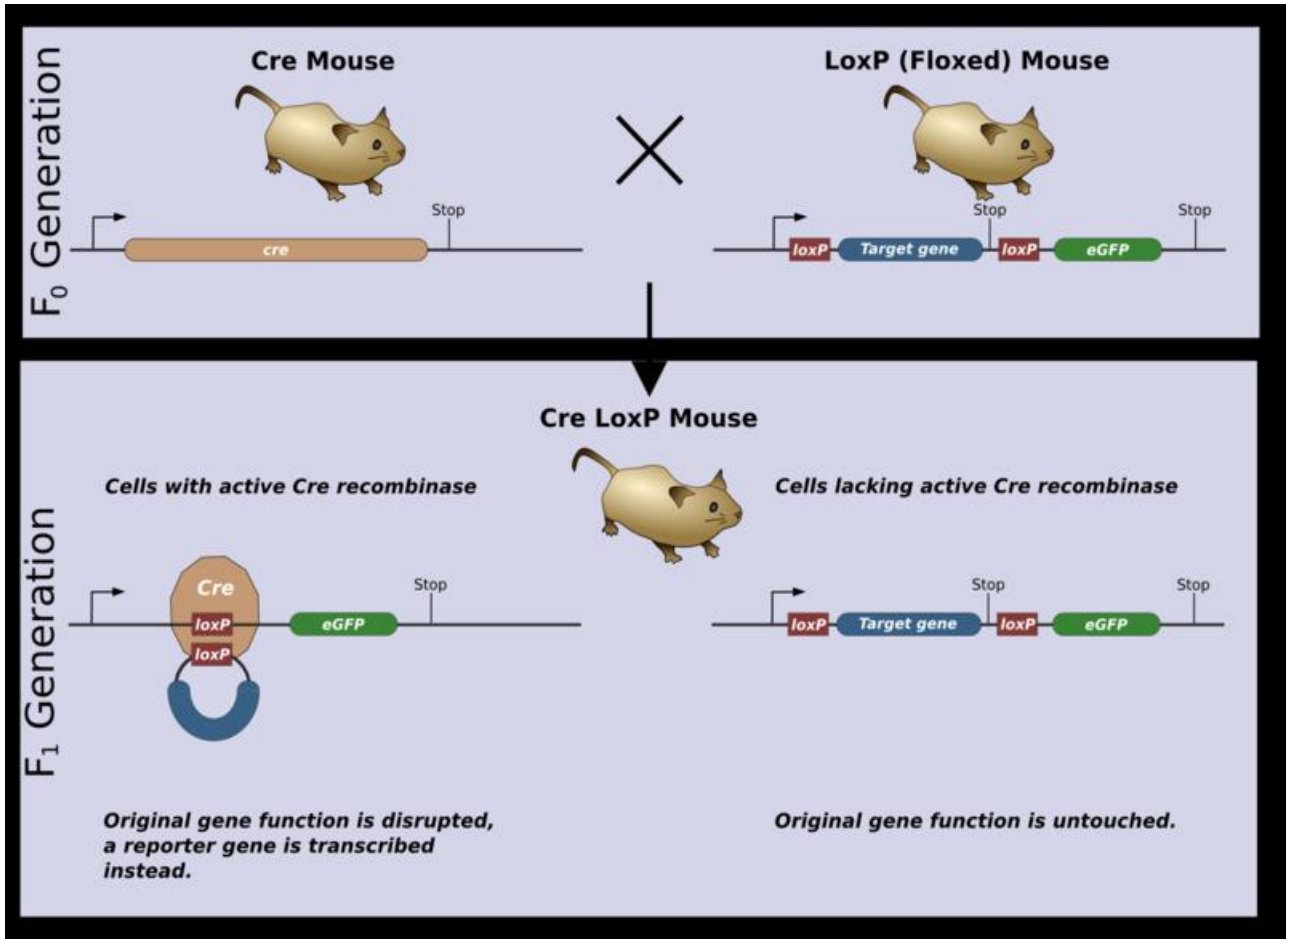
Knockout systems – the variation on the theme

Conditional gene targeting using the Cre/loxP system

(Tissue specific knockouts/
tissue specific promoters)

a transgenic animal, which is finally bred to an animal line expressing Cre under either temporal or spatial control.

Cre can also be ubiquitously expressed to obtain a knockout in all tissues, including the germ line.



Conditional Mutagenesis

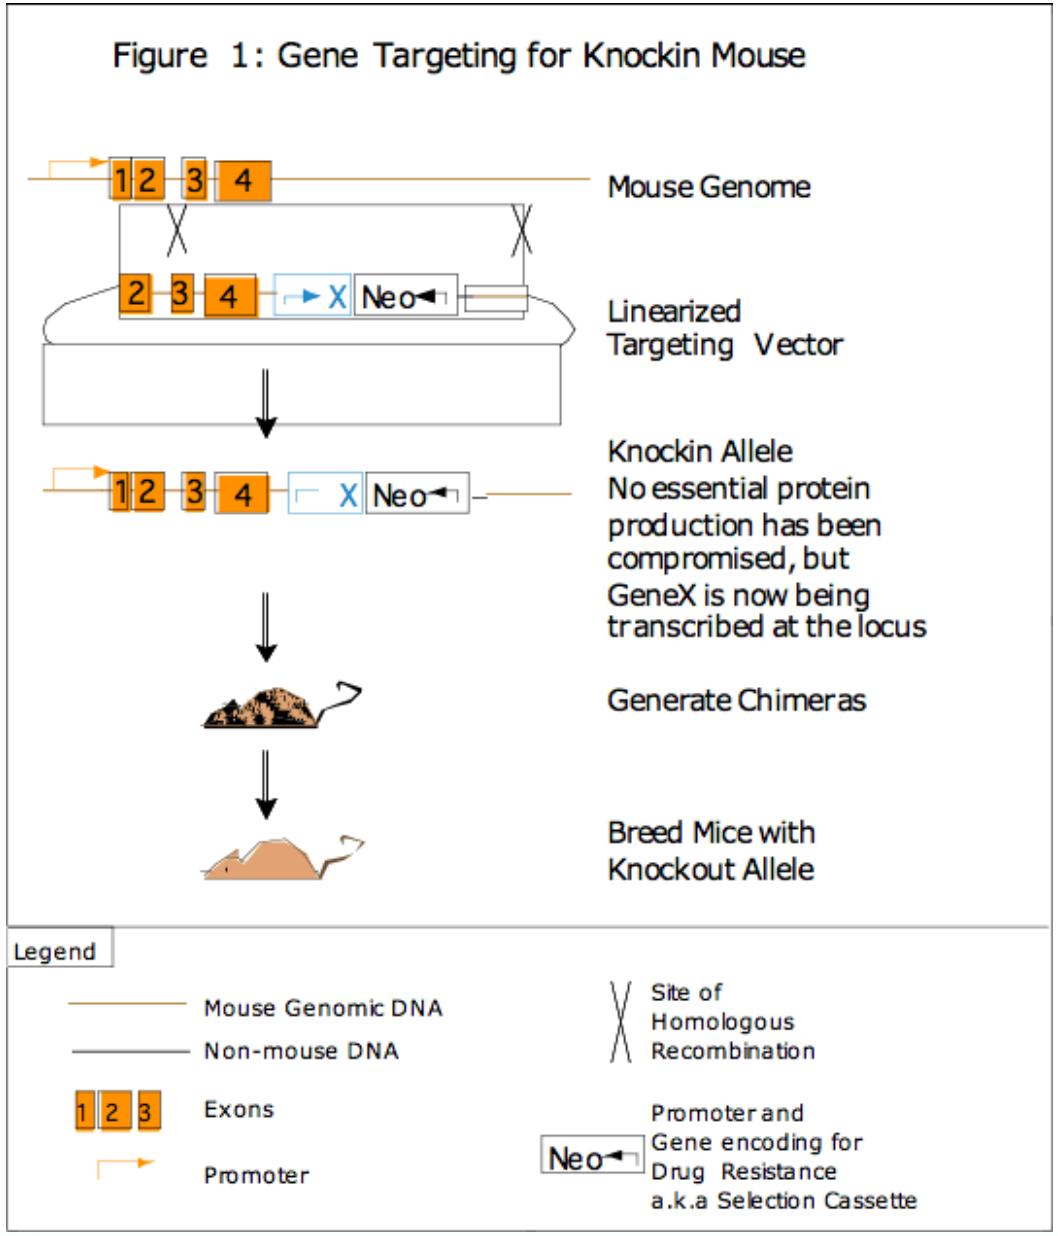
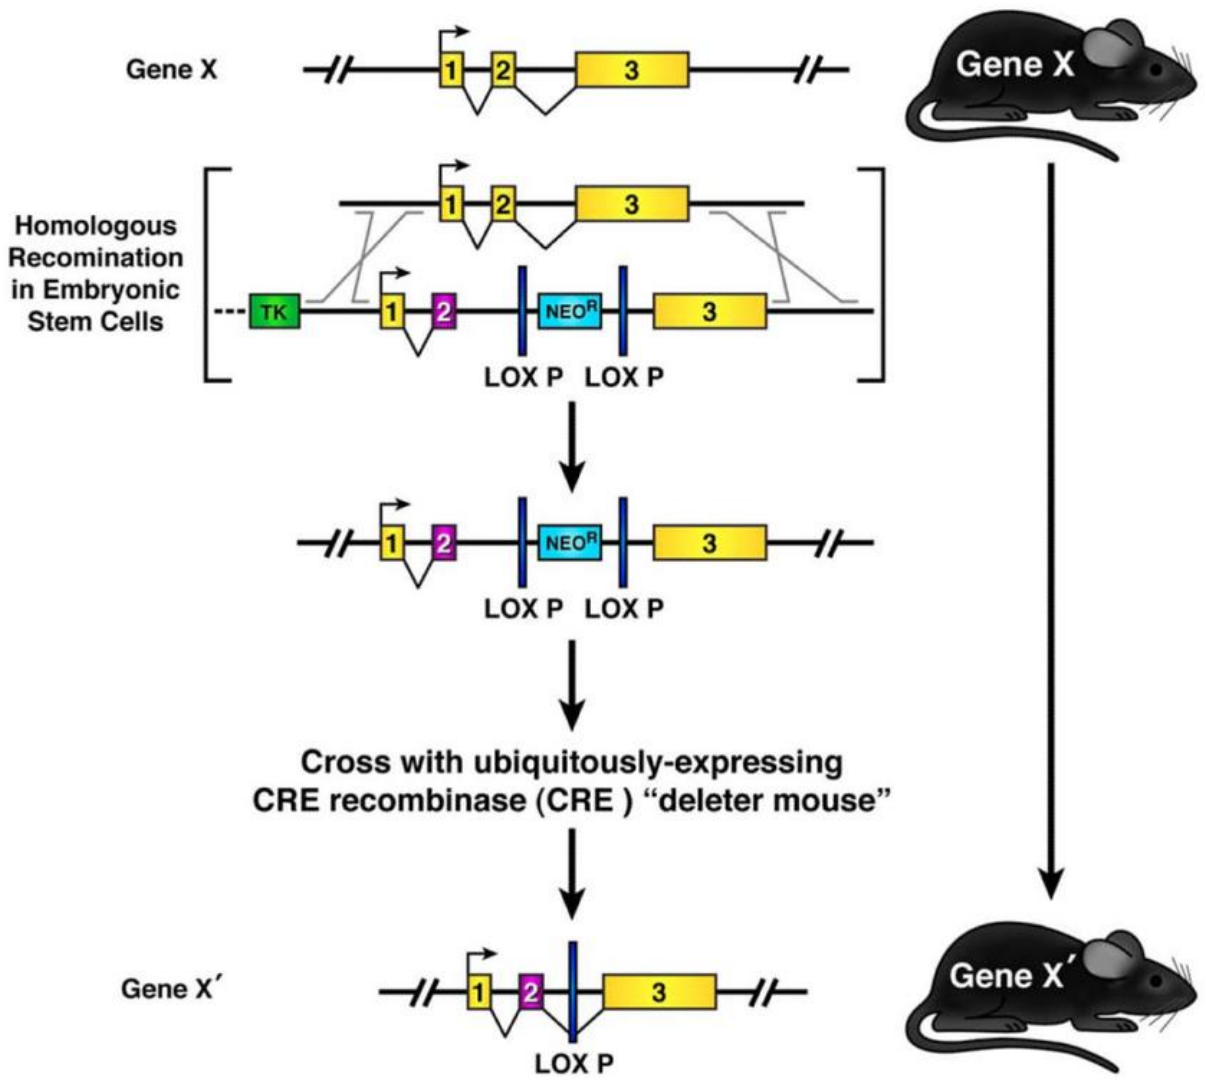
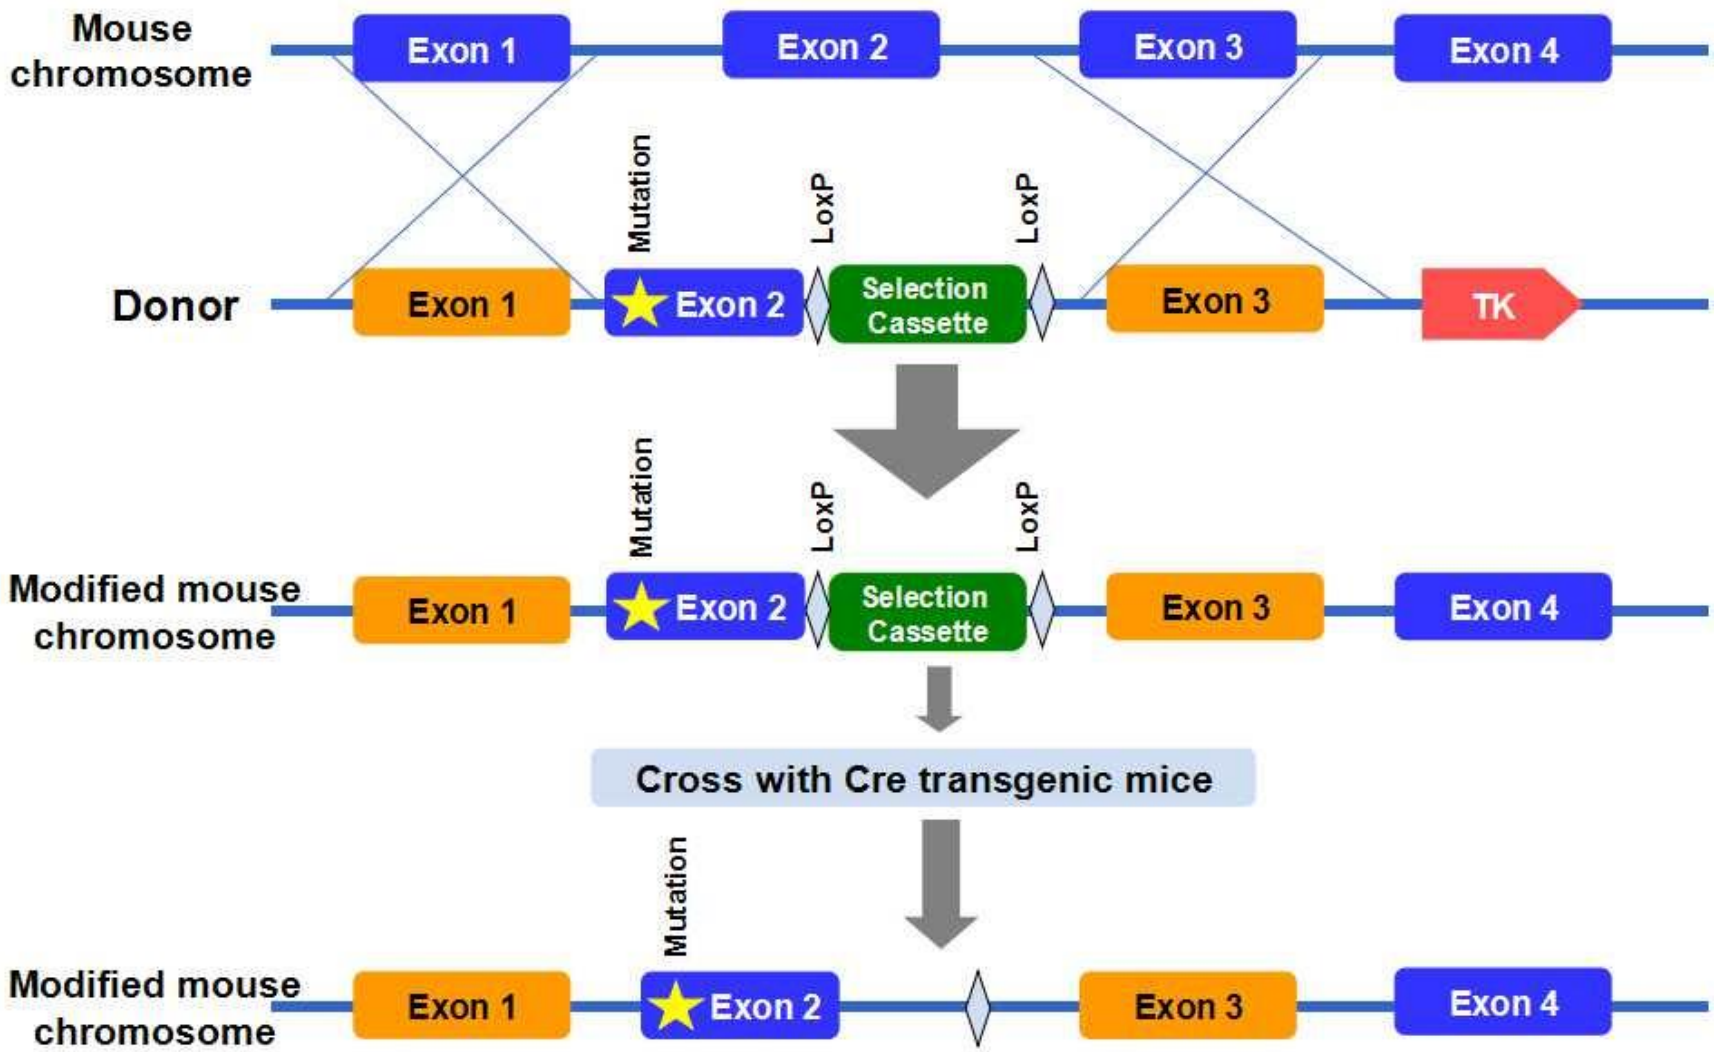
Knock In strategy

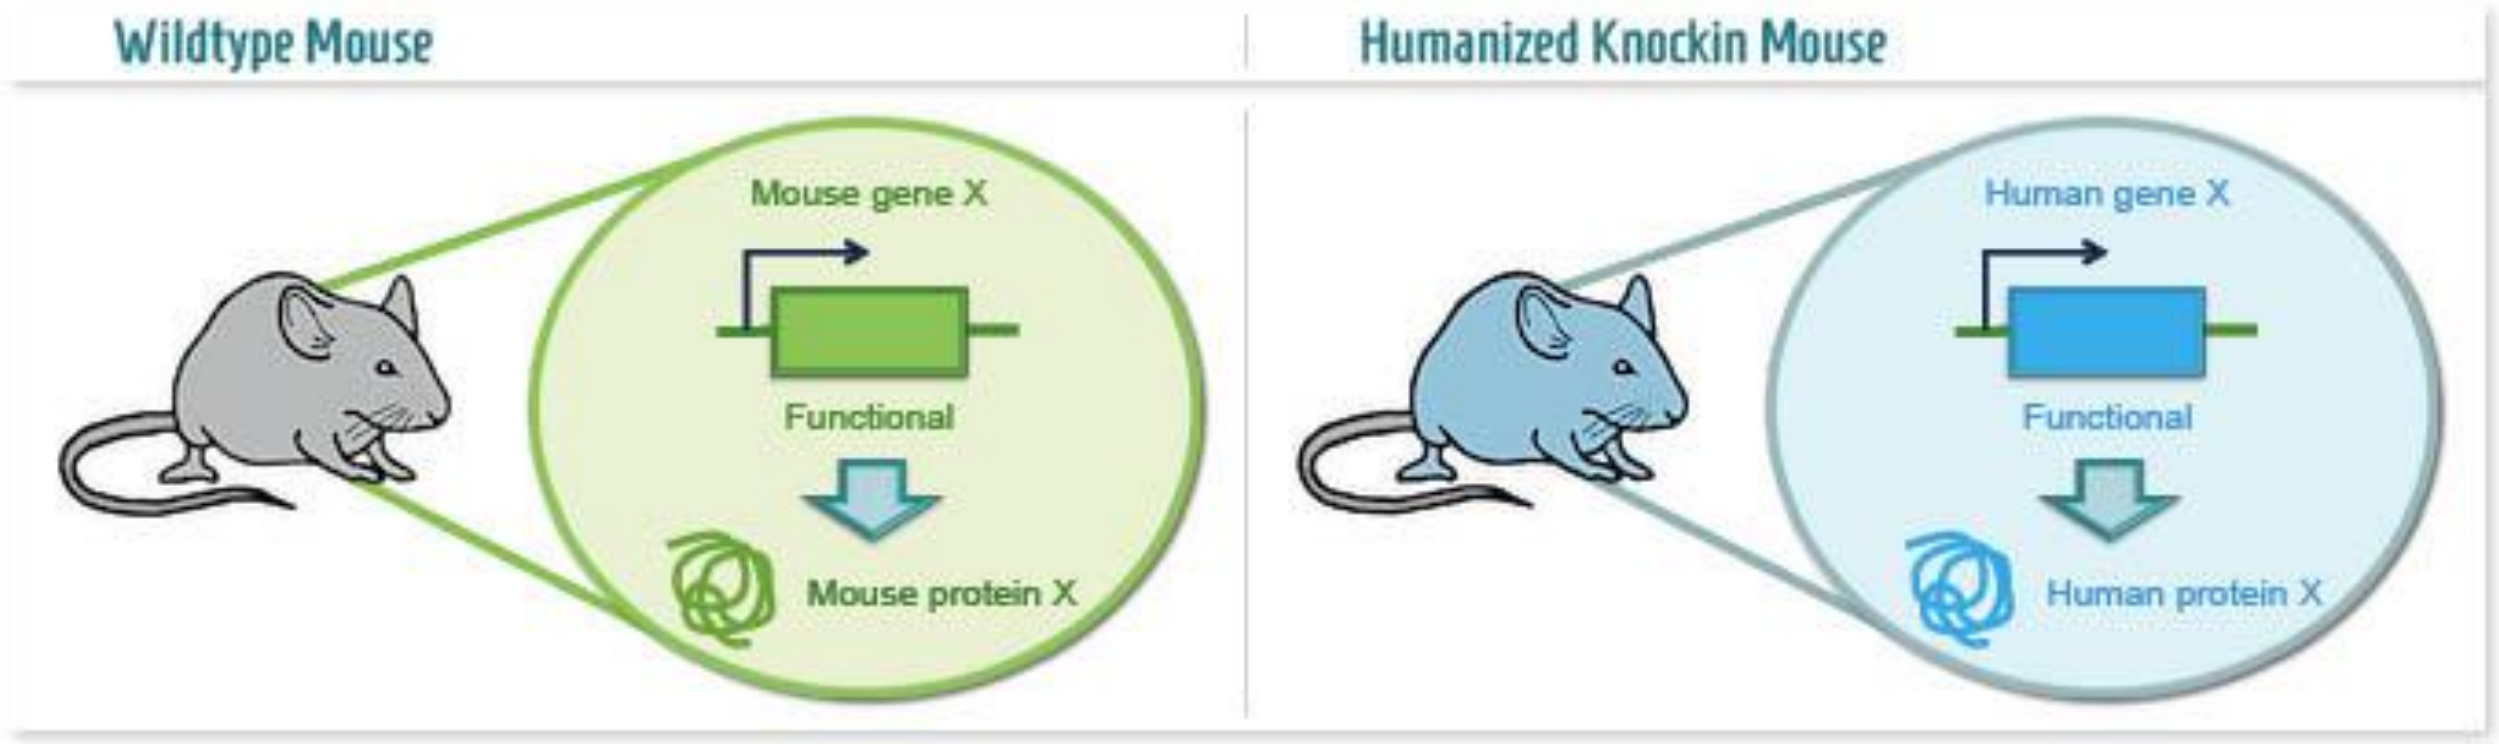




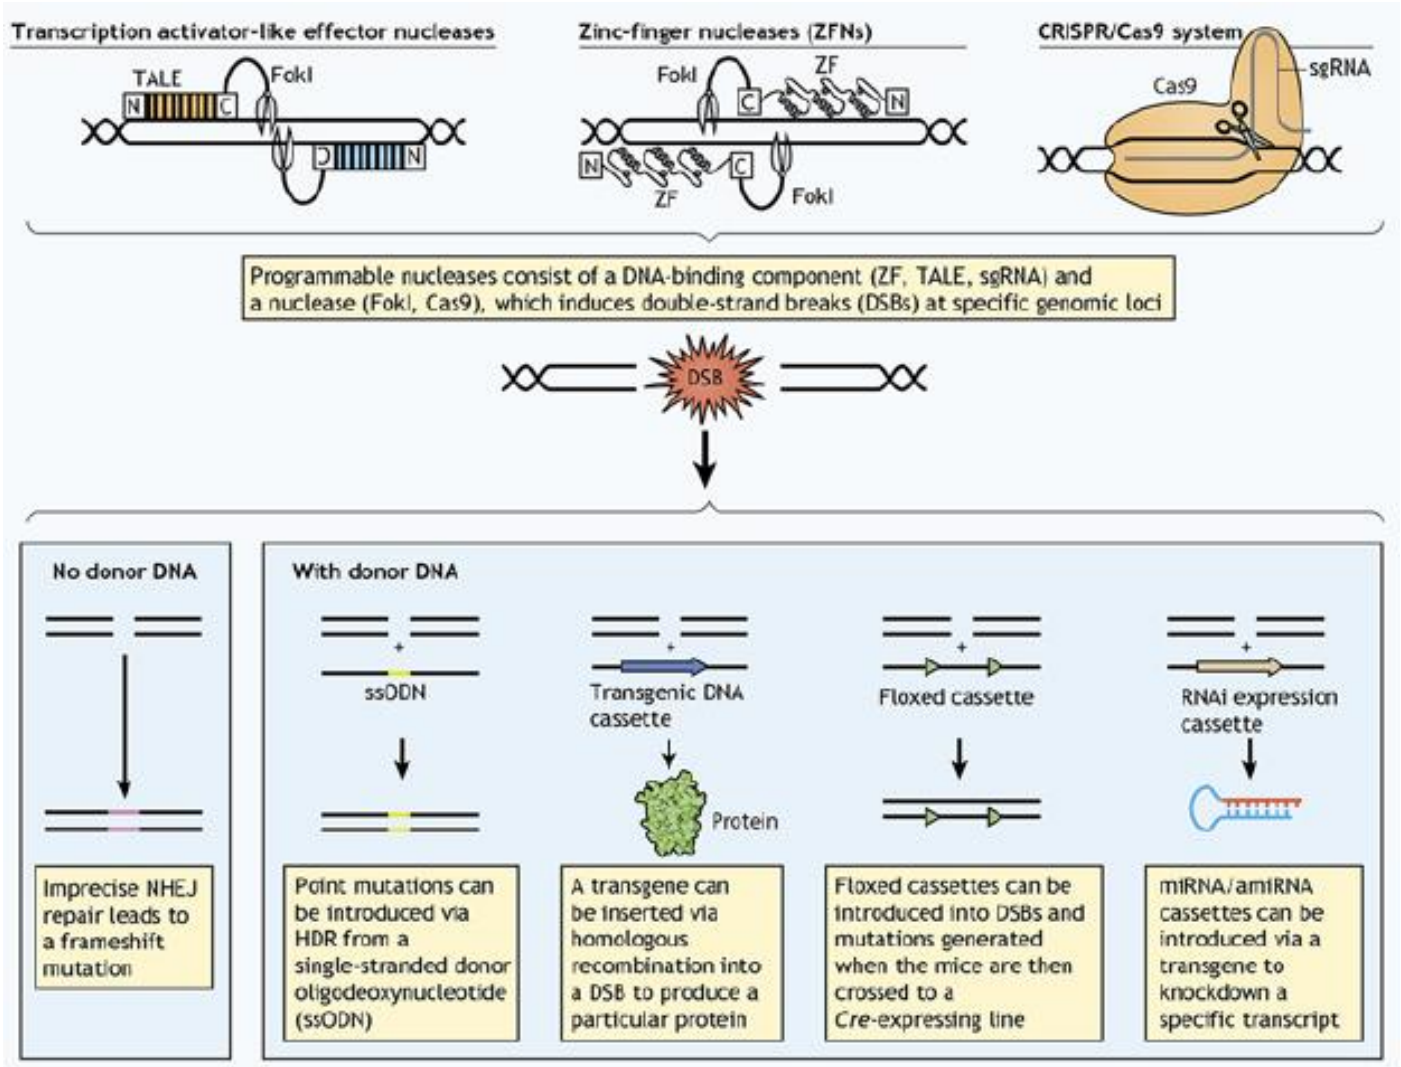
Knock In strategy: mutation



Humanized Knock In mouse



Genome Editing with Programmable Endonucleases



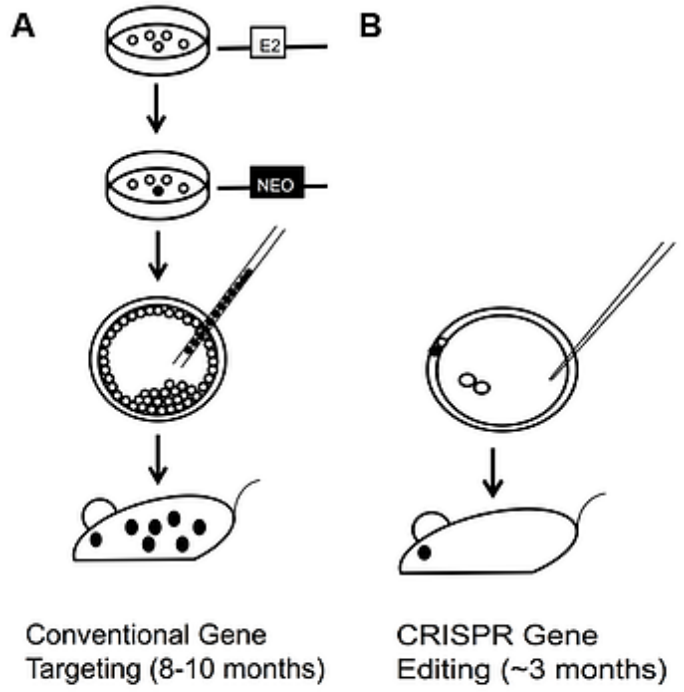


Figure 1: In conventional gene targeting (A), you must first generate your desired mutation in mouse ES cells, select for the mutation and inject the ES cells into a mouse embryo to create chimeric mice. This laborious process takes ~8-10 months. With CRISPR (B), you can inject CRISPR components directly into a zygote and obtain a knockout mouse in about 3 months). Image courtesy of Wenning Qin.

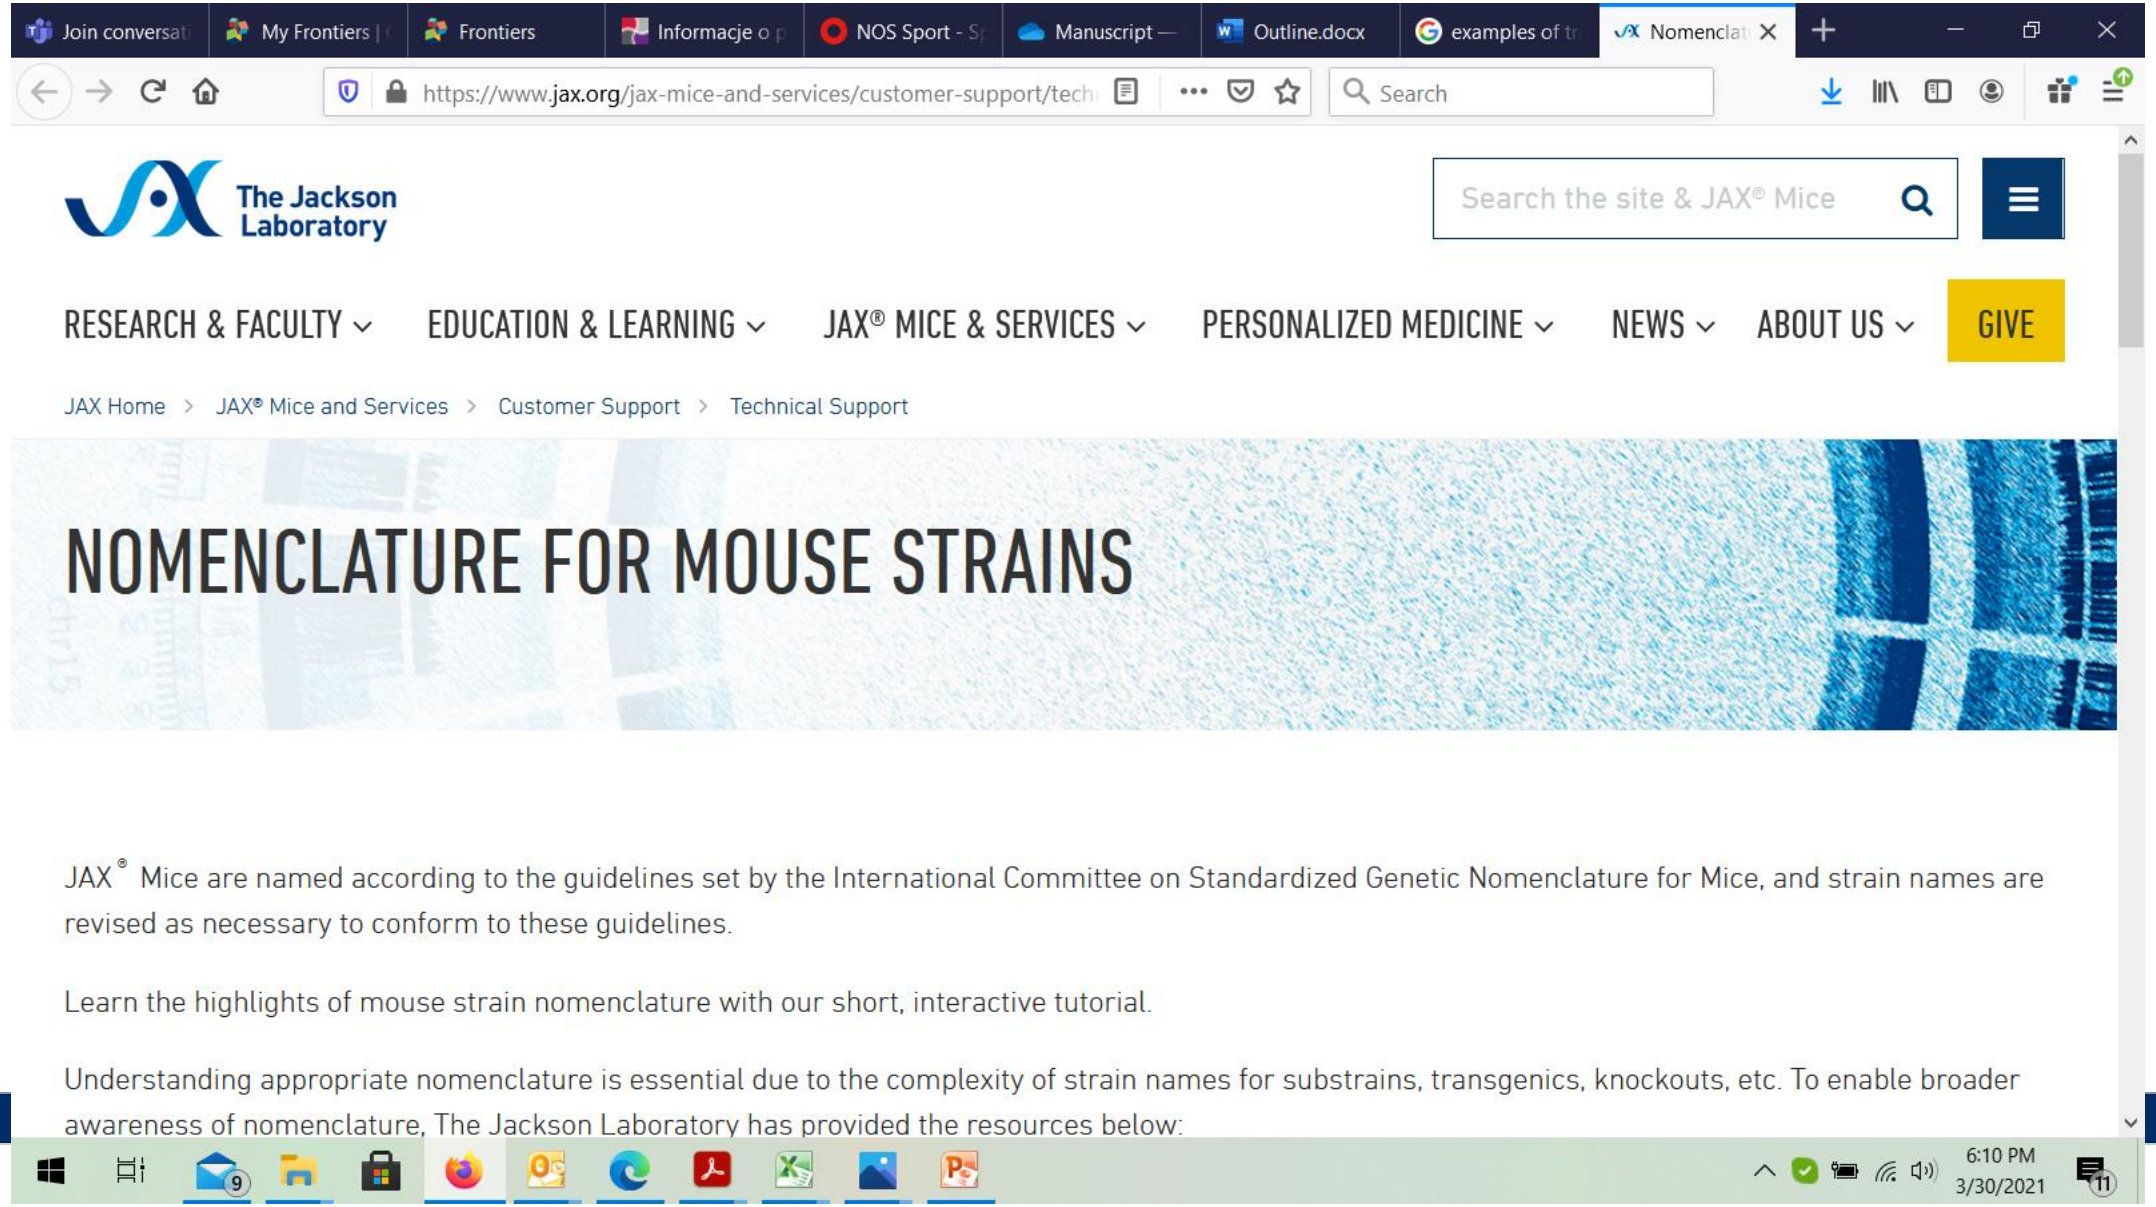
Mice

Mouse strains & mouse models

The survey results indicate that mouse is the overwhelmingly preferred laboratory animal;

The most widely used mouse strains are **C57BL/6 mice and BALB/c mice**. Other strains, such as A/J mice, **CD1 mice**, and ICR mice, were also used.

Mouse strains & mouse models



Mouse strains & mouse models

Data type	Count
Total mutant alleles (in ES cell lines and mice)	738,364
Mutant alleles in mice	24,339
Genes with mutant alleles	14,743
Genes with mutant alleles in mice	9,636
Mammalian phenotype ontology (MP) terms	8,744
Genes with phenotype annotations	8,903
Genotypes with phenotype annotations	43,335
Total MP annotations to genotypes	227,169
Human diseases with one or more genotypic mouse models	1,148
Mouse genotypes modeling human diseases	3,668
Quantitative trait loci (QTL)	4,696
Total recombinase (Cre)-expressing transgenes and alleles	1,739

[a] Data as of May 5, 2012, www.informatics.jax.org. New data are added to the MGI database daily; thus, actual counts will be higher than those shown here

[b] Mutant allele counts include spontaneous, induced (e.g., by ENU), and genetically engineered alleles. Transgenes, which are not part of the normal mouse genome, are not included

[c] Mutants present only in ES cell lines versus those created in mice or made into mice from ES cells are distinguished in several table counts. All phenotype-related data refer to mutations present in mice

Welcome to the NIH Mouse Initiatives Web site.

In March 1998, the NIH convened a group of scientists to develop priorities for mouse genomics and genetics resources. In response to the community's recommendations, the NIH has created a Trans-NIH Mouse Genomics and Genetics Resources Coordinating Group and a strategic implementation plan. For the convenience of all interested investigators, we have established this Web site as a central information resource. This site will provide information about funding opportunities; major mouse genomics and genetics resources; policies affecting resources; courses and scientific meetings related to the mouse initiative; and selected reports and publications. When appropriate, items not in response to the initiative, but which are deemed relevant to the initiative, will be posted. Posting decisions are made by a sub-committee of the Trans NIH Genomics Resources Working Group.
